## SELF DETERMINATION, NATIONAL See INTERNATIONAL POLITICS; NATION; NATIONALISM.

## SELIGMAN, C. G.

Charles Gabriel Seligman (1873-1940) was one of that remarkable group of young biological scientists (among them, W. H. R. Rivers, C. S. Myers, and William McDougall) who, under A. C. Haddon's inspiration, established scientific field work as the basis of professional anthropology in Great Britain during the first quarter of the twentieth century. Seligman's research broke ground for Malinowski's field work in Melanesia between 1914 and 1918 and for Evans-Pritchard's work in the Sudan twenty years later.

Seligman drifted into anthropology by chance. Originally trained as a physician, he had embarked on research in medicine when, in 1898, he learned of Haddon's plans for the Cambridge Expedition to the Torres Strait and volunteered to join it. At first Seligman confined himself to medical investigations, but his colleagues soon drew him into their anthropometric and ethnological studies. On

returning to England in 1899, he resumed his medical research until, in 1903, he met a wealthy American businessman, Major Cooke Daniels, and persuaded him to finance the expedition to New Guinea that resulted, *inter alia*, in *The Melaneians of British New Guinea* (1910). It was only after this expedition that he finally committed himself to anthropology by accepting the first lectureship in ethnology (in 1913 it became the chair of ethnology) established at the University of London.

In 1904 he married Brenda Z. Salaman, who collaborated in all his later field research and in many of his major publications. Her influence on their joint work was important: while Seligman himself had, for example, little interest in the minutiae of kinship custom, his wife, under the influence and instruction of Rivers, became adept in this branch of anthropology and took the responsibility for it. The Seligmans carried out a series of officially sponsored expeditions, to Ceylon in 1907–1908 to study the Veddās (see 1911) and their first expedition to the Sudan in 1909–1910. They made two further trips to the Sudan in 1911–1912 and 1921–1922.

In the intervals between these expeditions, while preparing their results for publication, Seligman continued his pathology researches and received for them, in 1911, the coveted distinction of a fellowship of the Royal College of Physicians, as well as other medical honors. In 1919 he also became a fellow of the Royal Society.

Like Haddon and Tylor, whose conception of a "science of culture" he admired, Seligman regarded anthropology as embracing every aspect of the life of the simpler societies (1926). He approached field work in the spirit of a Darwinian natural historian, considering a living society in terms of its geographical and historical setting as well as in terms of its racial composition, cultural make-up, and psychological foundations. Gifted also with a sensitive aesthetic judgment, Seligman built up a choice private collection of early Chinese art, notably of ceramic and bronze ware, and was thus drawn into research on Chinese history and civilization, a subject that was peculiarly congenial to his somewhat reserved temperament.

During World War I he joined the Royal Army Medical Corps and was, with Rivers, assigned to the staff of a hospital for victims of shell shock. Clinical experience convinced him of the general soundness of Freudian theory, and in later essays he applied psychoanalytical and related theories to the problems of ethnology.

**Descriptive ethnology.** Two features are characteristic of Seligman's anthropological and ethnological contributions: they are exploratory rather than definitive in aim, and they concentrate on factual data as opposed to theoretical interpretations and generalizations. Seligman's expedition to New Guinea set the pattern for his later ethnological work. Its aim was to establish the distinctive racial, social, and cultural features of the peoples of this region, with a view to their ethnological classification. All available sources were utilized, including the works of travelers, government reports, and notes and memoranda provided by long-resident missionaries and administrators, but the chief emphasis was on information obtained from native informants and eyewitness description.

Considering that the field work took less than a year and was carried out either in pidgin English or with the aid of often inadequate interpreters, the results are impressive. Malinowski (1922) paid tribute to the excellence of Seligman's observations. The data were for the most part new to anthropology. Where they were doubtful or defective, this was scrupulously indicated. Though Seligman made no attempt to investigate any subject in the depth achieved by the next generation of ethnographers, he did deal quite exhaustively with some topics (e.g., totemism), and he did not fail to draw penetrating conclusions, as in his elucidation of the powers and authority of chiefs.

Seligman's 1910 book remains a "basic and systematic work" on Melanesia (Elkin 1953, p. 47). It covers, in varying detail, every significant facet of tribal life: the geographical setting, racial composition, kinship and family structure, chieftainship and rank, property, trade, warfare, morals, magic and religion, material culture, feasts and ceremonies. It contains an important and comprehensive account (contributed by F. R. Barton) of the *kula*-type trading voyages of the Motu and an outline of Northern Massim culture on which Malinowski, and subsequently Reo Fortune, built. [See OCEANIAN SOCIETY.]

The field work that resulted in the two joint works entitled *The Veddās* (1911) and *Pagan Tribes of the Nilotic Sudan* (1932) followed the same procedures as those used by Seligman in New Guinea. *The Veddās* represents a valiant attempt to salvage what could still be found out about the culture and mode of life of the remnants of the aborigines of Ceylon, and it remains a standard work. The results of the Sudan venture, however, turned out to be more important. The three

Sudan expeditions, prepared for with exemplary thoroughness and supported by both the Sudanese government and British learned societies, were pioneer undertakings in every sense. In this huge territory, still barely pacified, living and traveling conditions were arduous. Communication with informants, in Arabic, was difficult; the Seligmans had only a working knowledge of the language and the southern Sudanese often no more than a smattering of it. Nevertheless, the Seligmans opened up an area until then ethnologically uncharted.

The works they published between 1911 and 1932 about this research made ethnological history. In particular, it was Seligman's description of the cult of Nyakang and the divine kingship of Shilluk (see 1911) that, as Evans-Pritchard commented, "brought . . . [divine kingship] to the notice of Sir James Frazer and into the main stream of ethnological theory" (1948, p. 1). *Pagan Tribes* summed up the results of the field research of the Seligmans and other investigators during the twenty years following the first expedition.

Seligman espoused the theory that successive waves of pastoral Hamites had, in the distant past, spread via the Horn of Africa westward and southward, mingling with the autochthonous Negro population to produce the Nilotes (Shilluk, Dinka, Nuer, etc.) and Nilo-Hamites (Bari, Lotuko, etc.) and the chain of peoples in the Great Lakes region stretching through the Hima elements (e.g., in Ankole) to the Masai, all distinguished by their greater or lesser adherence to pastoralism (1913). Conjectural as the theory of Hamitic migration may be, the ethnic classification remains valid, as its continued use (e.g., in the Greenberg language classification) testifies. The theory became a cornerstone of Seligman's synoptic review of the peoples and cultures of Africa (1930). These are divided into six major ethnic clusters—the Bushmen and Hottentots, the true Negroes of west Africa, the Hamites (eastern and northern), the Nilo-Hamites and Nilotes, the Bantu, and the Semites. It is a singular feat of compression and still the best over-all introduction to African ethnology. [See AFRICAN SOCIETY, article on SUBSAHARAN AFRICA.]

**Historical ethnology.** Seligman's concern with historical ethnology grew naturally out of his descriptive studies. It was also a response to the challenge of the extreme diffusionist theories advocated by Elliott Smith and Rivers. Seligman flatly rejected these theories, contrasting them with genuinely historical reconstruction based on geo-

graphical connections and evidence derived from material culture and institutional relationships (1927). Thus, when he himself carefully considered the evidence for the supposed Egyptian origin of divine kingship in Africa, he came to the conclusion that its most characteristic features go back to an "old and widespread Hamitic belief" to which some specifically Egyptian elements only later became attached (1934). [See KINGSHIP.]

It was in the pursuit of these and other historical and distributional associations that Seligman undertook his investigations into prehistory (e.g., of Egypt and the Sudan) and his studies of artifacts and *objets d'art*. Coupled with his passion for Chinese art and civilization, these studies culminated in his joint paper, with H. C. Beck, on Chinese glass (1938). Here Seligman sought to clarify the routes and modes of transmission by which various products and technical skills reached China from western Europe even before the second century B.C.

**Physical anthropology.** The investigations in physical anthropology that formed for Seligman the necessary basis for the organization of cultural and historical data now appear relatively crude. Without such modern techniques as genetic analysis of blood groups, he obtained anthropometric and anthroposcopic data that have only limited validity.

**Cross-cultural psychology.** Seligman's psychological investigations began with the application of sensory discrimination tests to the Veddas; the results were discouraging. Later he became convinced that the psychology of the unconscious was the key to many fundamental problems of anthropology, and in his first presidential address to the Royal Anthropological Institute he stressed "the borderland where social anthropology, psychology, and genetics meet in common biological kinship" (1924, p. 13). (He reverted to this theme in his Huxley Memorial Lecture in 1932). He enlisted the aid of field ethnologists, psychoanalysts, orientalist, and a variety of other specialists, as well as laymen, in the pursuit of these inquiries. Malinowski was one of the many who owed his introduction to psychoanalysis to Seligman (Malinowski 1927, preface).

Guided by Freud's theory, Seligman produced evidence from many different cultures for the universality of such "type" dreams as those involving the loss of teeth, flying, and raw meat. He found that conventional interpretations of such dreams often implicitly recognized their symbolic nature. He inferred that there is in the unconscious of all

peoples "a proved common store on which fantasy may draw" in the construction of myth and ritual beliefs and even of technical processes (1924, p. 41). His interpretation of magical rites was that they are "symbolic dramatizations" that drain away unconscious anxiety and that are thus comparable to neurotic symptoms. Taking a different perspective, he assembled cross-cultural evidence to test the universality of the stages of individual psychosexual development postulated in Freudian theory. Emphasizing the scanty and conflicting nature of the ethnological data then available, he concluded that they tended to confirm rather than to refute (as Malinowski maintained) the Freudian hypothesis (1932). Also impressed with Jung's extrovert-introvert dichotomy of temperamental types, he applied it in tentative studies of art styles, of the national character of the Japanese, and of psychosis in different cultural settings (1931). He concluded that psychosis was rare in stable primitive societies but tended to emerge as a result of conflicts engendered by contact with European culture, conflicts he connected also with the then incipient nativistic movements now called cargo cults.

These studies claimed no more than to demonstrate the significance of psychoanalysis for anthropology at a time when there was a strong reaction in British anthropological circles against such an application of psychoanalytic theories. [See CULTURE AND PERSONALITY.]

Just as Seligman rejected all-embracing diffusionist explanations of ethnological connections, so also he was chary of evolutionist constructions of the kind favored by Frazer and L. H. Morgan. With his strong biological bias, he saw living mankind as a single species with common and uniform mental and physical capacities and dispositions but distributed over the globe in racially diverse and culturally varied communities in different phases of historical development. Though Malinowski's functionalism grew up directly under his eyes, and not without his sympathy, he never aligned himself with this movement; he was too much of an empiricist. The task of scientific ethnology, as he saw it, was to approach particular areas and particular problems by as many methods and from as many angles as could serve to reveal useful data and throw light on them.

## SELIGMAN, EDWIN R. A.

Edwin Robert Anderson Seligman (1861–1939), American economist, was editor-in-chief of the *Encyclopaedia of the Social Sciences* from 1927 to 1935 and McVickar professor of political economy at Columbia University from 1904 to 1931. He was born in New York City, where his father was a banker prominent in national and international circles. Until the age of 11, Seligman was educated at home, his tutor being Horatio Alger, Jr. From the Columbia Grammar School Seligman entered Columbia College, shortly after his fourteenth birthday, and received his A.B. in 1879. He became proficient in the German, French, Italian, Spanish, Russian, and Dutch languages. After attending the universities at Berlin, Heidelberg, and Paris, in 1882 he began graduate studies in economics at Columbia and, "to have a second arrow in the quiver," also studied law. In 1884 he received both an M.A. and an LL.B., and in 1885, his Ph.D. Also in 1885 Seligman was admitted to the New York bar and was appointed lecturer in economics in the newly formed faculty of political science at Columbia University. Three years later he became adjunct professor of political economy; in 1891 he was appointed professor of political economy and finance, a post he held until 1931. He served for many years as chairman of the department of economics. In the 1920s Seligman received honorary doctoral degrees from the universities of Paris and Heidelberg.

Seligman's immense energy, wide-ranging interests, and sense of social responsibility led him to participate in the work of academic, governmental, and civic organizations and committees, especially those promoting social reform. He was a member of the Social Reform Club of New York City, the Educational Alliance, the Political Economy Club, Greenwich House (a settlement house), and the Society for Ethical Culture and served as president of the last two organizations and as chairman of the Bureau of Municipal Research. He was secretary of the Committee of Fifteen, whose 1902 report, *The Social Evil*, revealed the economic links of corruption between prostitution and the New York City police.

Seligman was a leader in the founding of the American Economic Association (AEA) and served as its president from 1902 to 1904. He also served a term as president of the National Tax Association, from 1913 to 1915. He helped to establish both the City Club of New York, which has worked for the improvement of civic conditions since its founding in 1892, and the American Association

of University Professors (AAUP), in 1915; he was AAUP president from 1919 to 1920. Seligman was an effective champion of academic freedom. He was the chairman of the AEA committee that wrote the first report on this subject in the United States, the occasion being the dismissal of Edward A. Ross from Stanford [see the biography of Ross], and he was also chairman of the AAUP committee that in 1915 wrote the fundamental *Report on Academic Freedom*. In the field of his specialty, public finance, Seligman was also active: he was a member of special tax commissions of New York State in 1906 and 1930; chairman of the Mayor's Commission on Taxation and Finance, New York City, 1914–1916; expert adviser to the New York State Joint Legislative Tax Committee, 1919–1922; member, with Bruins, Einaudi, and Stamp, of the League of Nations Committee on Economics and Finance, 1922–1923, which produced the report *Double Taxation*; and, in 1931, consultant to the government of Cuba.

When the study of political economy at Columbia became more specialized, Seligman accepted responsibility for the then neglected field of public finance, but he also developed a continuing interest in the history of economic doctrine. This interest led to his giving a course on this subject and to his famous collection of books, pamphlets, and other items on economics, now in the Columbia University library. He was one of the small group of scholars that established economics as a recognized discipline in the United States.

Seligman's intellectual influence was wide, several of his books being translated into more than one of the leading languages. It has extended to the present, largely through his contributions to the history of economic thought, reflecting the stimulus he received at Paris, and through the clarity and appropriateness of his conceptual and categorizing contributions. The former achievement is illustrated by his article "On Some Neglected British Economists" (first published in 1903; see [1886–1925] 1925); the latter, by the introductory chapter of *The Shifting and Incidence of Taxation* (1892), "The Classification of Public Revenues" (see 1895), and his analysis of ability-to-pay and faculty concepts in taxation (see 1928). More than one present-day treatise, particularly in Europe, refers frequently to Seligman's conceptual and historical contributions.

Although Seligman did not entirely escape error in attempting to apply the newly developing price theory to the substantive part of *Shifting and Incidence*, he did enliven the doctrinal atmosphere with his vigorous approach and equally vigorous coun-

terthrusts when challenged. His exchanges with Francis Y. Edgeworth were enlightening. Seligman's treatise was a pioneering achievement in its treatment of the history of doctrine and in its arrangement and development of a difficult subject.

Seligman's writings on taxation, quite influential in their day, are less cited now, either because the paths he opened up were later explored further by so many, or because the terminology he originated soon passed into common use, or because the reforms he advocated were adopted. Among his useful contributions were his *Progressive Taxation in Theory and Practice* (1894), *The Income Tax* (1911), and his writings on the property tax, all of which also embody his desire, arising from the contrast between his American and European training, to build a bridge between the deductive and the historical-comparative schools, with emphasis on the latter, which he felt had been neglected in the United States.

Seligman also wrote extensively outside public finance. Some of these contributions were widely accepted for many years, especially *The Economic Interpretation of History* (1902), which proved influential in developing analysis in this area. Among his interests in applied economics were problems of railroads, unemployment, the fur and jewelry trades, installment selling, agriculture, and resale price maintenance.

It was this catholicity of interest, together with an exceptional erudition and a broad acquaintance with scholars of many countries, that enabled Seligman, toward the close of his career, to make one of his most notable contributions, as a chief promoter of, fund raiser for, and editor-in-chief of the English-language *Encyclopaedia of the Social Sciences*, to which he also contributed articles and biographies.

Seligman, formal in the lecture room, was a man of warm temperament, with an intense personal interest in the material and intellectual welfare of his students. Through them and through his own writings, he opened up the field of public finance in the United States both to scholarship and to measures of reform.

#### SEMANTICS AND SEMIOTICS

Semiotics is the study of sign phenomena. Specialized research into natural human language—the semiotic phenomenon par excellence—constitutes linguistics; within linguistics, semantics is

concerned with the conveyance of meaning by the grammatical and lexical devices of a language. According to the theoretical, descriptive, and historical slants of linguistic investigation, semantic problems respectively assume a general, synchronic, or diachronic character.

The self-evident systematicity of grammatical phenomena has always been conducive to their relatively reliable semantic analysis. When it comes to the looser domain of vocabulary, however, the obscurity of the underlying structure quickly embroils semantic analysis in some of the more inconclusive epistemological controversies of social science. While vast supplies of raw semantic data repose in dictionaries of various languages, there is no consensus among linguists on a coherent theory in accordance with which this material can be analyzed and compared for purposes of generalization.

**Definition and components of sign.** The key term in semiotics is "sign." By all accounts, a sign must consist of at least (1) a perceptible impact on one of the senses of the "receiver" and (2) a content that is signified. First distinguished by the Stoic philosophers, then recognized in European medieval literature as *signans* and *signatum*, these minimal components of the sign have reappeared in modern theory under such labels as *signifiant* and *signifié* (Ferdinand de Saussure) or "sign vehicle" and "designatum" (Charles W. Morris). (Under appropriate contextual conditions, the absence of a *signans* itself functions as a "zero" sign vehicle. It is often utilized in language with great effectiveness.) A particular occurrence of a sign is customarily called a "token," while the class of all occurrences of the sign is called the "type." According to this usage, the total number of words in a text is the number of word tokens, whereas the number of different words in the text is the number of word types.

Signs may be classified by the sense on which the sign vehicle impinges: they can be visual, auditory, etc. A sign may then have equivalent sign vehicles in the same or another modality. Full equivalence is illustrated by a plain transposition cipher (based on a novel utilization of the same graphic system) or by a light blinking and a buzzer sounding in response to the same Morse code impulses. The correlation, on the other hand, between written and spoken language is far from one-to-one.

**Designation and denotation.** A crucial issue for most students is the distinction between what particular sign tokens denote, or refer to, and the

constant capacity of the sign type to denote, or refer. The former relation has been treated under the heading of "denotation," or reference; the latter has been called "designation," or meaning (in the narrow sense). Thus, the designatum (2a) of a sign type—what the sign designates—can in theory be specified by (2b) the conditions under which, or the "objects" with reference to which, the tokens of the sign would be said to denote in a truthful way. Every sign by definition designates something, but some signs have no real things, or "denotata," to refer to (e.g., *unicorn*), and every sign may on occasion be used without denoting (e.g., *milk* when no actual milk is being referred to) or without denoting truly (e.g., *milk* used with reference to water). A perceptible discrepancy between what a sign type designates (2a) and the denotatum of one of its tokens (2b) seems to be involved in such effects as metaphor and irony, as well as in perversions of communication (lying).

If the designatum is thought of as the class of denotata for which the sign vehicle is a name, the specification of the designatum can correspondingly be visualized as extensional (by enumeration of the members of the class, i.e., the denotata) or as intensional (by stating the properties shared by all members of the class, and only by them). The ability of living beings to form intensional class concepts—an ability which has not so far been mechanically simulated or abstractly reconstructed—reaches the most extraordinary proportions in man. There is evidence that concept formation proceeds with particular efficiency if there are signs present for which the concepts can become the designata.

The theoretical distinction between (2a) designata and (2b) denotata is also essential for accommodating the fact that something can be a true denotatum of more than one simple sign (e.g., *car* and *vehicle*) or of various compound signs (e.g., *female sheep* = *ewe*).

**"Reductionist" approaches.** The minimal account of signs in terms of sign vehicles and designata has been variously enriched; the richer schemes have in turn been subjected to reduction along several lines. Two further factors of the sign, essential in some accounts, such as that of Charles S. Peirce, are (3) the interpreter, or the individual for whom the pairing of a sign vehicle and a designatum functions as a sign, and (4) the interpretant, corresponding to the interpreter's (perhaps unconscious) reaction to a sign. One way of explicating this reaction is to understand "interpretant" as the interpreter's private translation of a sign into other signs. Anticipating the discovery

of neurological correlates of "understanding" and similar psychological phenomena, some theorists have apparently identified the interpretant of a sign with its translation into the (still unknown) neurological code.

Related in spirit is the effort of experimental psychologists to specify the meaning of a sign in terms of attitudes taken toward it, emotions induced by it, or further signs automatically evoked by it—as displayed, for example, in a semantic differential (Osgood et al. 1957) or a free-association test. Thus, whereas the designatum of a sign was traditionally understood to be given by the verbal definition of the sign, behavioristic psychology has endeavored to bypass the designatum (2a) in favor of the effect of the sign (4), regarding the latter, if not as more accessible to study, then at least as the less objectionable construct. A kindred suspicion of constructs has moved skeptical empiricists—in eighth-century India as in twentieth-century England and America—to reject designata as needless entities and to account for the use of sign tokens (acts of "reference") merely in terms of the sign vehicle (1) and the actual denotatum or "referent" (2b).

Such impoverished theories may cover certain "straightforward" uses of natural language and may serve the rationalization of scientific discourse. But an account that fails to treat the designatum as a component of the sign, distinct from both its denotatum and its interpretant, cannot adequately deal with such phenomena as reasoning or humor, and is therefore incommensurate with the complexity and subtlety of human semiotic abilities.

In general it should be admitted that the denial of the *sui generis* nature of communicative activity and the reduction of sign phenomena to some more general kind of behavioral phenomenon have produced no marked success in either theory or research practice. A sign type is not always—perhaps only rarely—correlated with a class of specific stimuli or of overt responses. Nor is a sign token a counterfeit or avowed "substitute" for a "real" thing; it is, at most, a "representative" of the real things for purposes of communication qua communication, and in contrast to the case of other substitutes, the real thing will not do where a sign is required. When we reflect, furthermore, that the denotata of most sign tokens of language are neither "real" nor "things" nor even necessarily existent, it becomes evident that if sign tokens "stand for something," they do so in a way that differs from other modes of substitution.

**Symbolic and less-than-symbolic signs.** A sign with an intensional class for a designatum and without contiguity or similarity between its vehicle

and its denotata is called a symbol. Other, less fully developed forms of sign may be classified as indices, icons, names, signals, and symptoms.

A sign is said to be an index rather than a symbol insofar as its sign vehicle is contiguous with its denotatum, or is a physical sample of it (a swatch of cloth as a sign of the color or an onomatopoeic word as a sign for an animal sound). In the case of some indices the contiguity between the sign vehicle and the denotatum is suggestive rather than literal, as in a directional arrow which guides the viewer's eyes toward a target. In general, when a sign vehicle is paired with a denotatum as a matter of necessity, the involuntary, mechanical nature of this connection may be viewed as an abstract analogue of physical contiguity; automatic, nonarbitrary signs are hence said to be merely "symptomatic" rather than fully symbolic.

Natural languages have been observed to contain indexlike signs which conventionally direct the listener's attention to a time, a place, a participant in the discourse, or a part of the interlocutor's field of sight. These are studied under the heading of "deictics" or "shifters"; English examples are *now*, *here*, *I*, *this*.

When there is a geometric similarity between a sign vehicle and its denotata, the sign is said to be *iconic*. Such similarity would be exemplified by a system in which, let us say, large things are signified by long words, small things by short words, or in which plurality of denotata is signified by repetition of the sign vehicle. A realistic painting is a highly iconic sign; in human language the role of iconicity is marginal.

A theory of signs which conceives of a designatum as an intensional class must also allow for a more "stunted" type of sign which has an extensional class as its designatum. Such signs are generally called "(proper) names." The individuals, whether one or many, which are truly denoted by a proper name have no common property attributed to them except "answering" to that name.

For discourse about signs it is necessary to use signs for referring to signs. For this purpose a sign vehicle is commonly employed as an index of its own sign. In discourse about languages it has long been found useful to discriminate between the use of signs and the mention of signs. A sign employed as a name for itself is commonly said to be used "metalinguistically"; a specialized language for communication about another language (the "object language") is called a "meta-language."

**Overlapping semiotic functions.** In a particular communicative act a token may at the same

time function as a symbol and as a less-than-symbolic sign. Thus, a sign token may trigger, mechanically or conventionally, some action on the part of the receiver; it then functions as a "signal." In many languages, the imperative is a grammatical device for endowing a symbol with signal value, but a complex symbolic sign without special markers (e.g., *I am ready*) may function secondarily as a signal for some action. Similarly, an interjection of pain, to the extent that it has a coded form in the language (e.g., English *ouch* vs. German *au*), is conventionalized and hence symbolic; insofar, however, as it is uttered involuntarily, it is a symptomatic (indexical) sign. Every layman develops considerable skill in synchronizing the "symbolic" analysis of speech with a judgment of voice quality, tempo, and other involuntary aspects of the utterance as symptoms of the speaker's state. Specialists have learned to interpret in depth certain "covert," involuntary statistical properties of speech to which ordinary hearers may not respond even on an unconscious level.

Not only do symbolic functions overlap with symptomatic and signaling sign functions, but the sign may, primarily or secondarily, serve altogether noncommunicative functions as well. Superimposed upon linguistic utterances with symbolic value may be aesthetic or magical functions (poetry, incantations). Contrariwise, behavior patterns and artifacts intended for other primary purposes may acquire a signlike aspect: a garment, worn to provide warmth, may by its shape symbolize the wearer's acceptance of, or rebellion against, the conventions of society; an automobile, primarily a means of transport, may by the redness of its color symbolize its user's status as fire chief. The development of general and comparative semiotic research would seem to depend to a large extent on the inclusion of such "mixed" semiotic phenomena.

**Paradigmatic relations between signs.** Two or more signs each or all of which can occur in the same context are said to form a paradigmatic set. Membership in such a set helps to determine the identity of a sign, since the definition of its sign vehicle and its designatum may be formulated in terms of the discrete differences between them and the vehicles and designata of other signs in the same set. Students of language have capitalized on the paradigmatic nature of their material by organizing the description of sign vehicles and designata around those minimal distinctive differences of sound and meaning which contrast one item with another within the total system. In the investigation of vocabulary, this approach has led

to the concept of "word fields," i.e., semantically related groups of words, and has yielded a sizable literature since it was initiated in the 1930s by Jost Trier. However, the more populous and amorphous a paradigmatic set of elements, the less certain is the organization of their contrastive features. Hence word-field studies are beset by a strong streak of impressionism, exacerbated by the concentration of research on early stages of languages for which the benefit of native speakers' intuitions cannot be drawn upon.

Being different from each other is, of course, only the most general relation between signs in a paradigmatic set. More specific relations are determined by the conditions under which two signs are interchangeable: symmetrically in the case of perfect synonyms, asymmetrically in the case of superordinates and subordinates (e.g., *gun-rifle*), and at the cost of reversing the truth value of the message in the case of antonyms. The way in which these more specific relations organize a set of terms may be different in various languages. Thus, two languages may have terms for "cattle," the difference between them being that in one of the languages, but not in the other, "cattle" includes "sheep" as a subordinate.

Proceeding from their experience with folk classification in the field of kinship, anthropologists (particularly in the United States) have analyzed selected sectors of vocabulary in the form of taxonomies—systems in which all terms are governed by a subordinate-superordinate relation (Conklin 1962). It still remains to be shown whether this descriptive format is easily applicable to lexical domains less closely structured than those dealing with kinship, color, weather, illness, plants, and animals. It is clear, moreover, that studies of lexical systems oversimplify the problem unless they take full account of the omnipresent facts of polysemy, grammatical specialization, and phraseological specialization (discussed below). Meanwhile the introduction of certain nonsymmetrical operations to supplement the traditional algebra of classes promises to reduce some of the counterintuitive excesses of earlier sophisticated nomenclature analysis (Lounsbury 1964).

**Sign tokens in sequence.** The patterning of sequences in which sign tokens may be transmitted ranges between two extremes. At one pole lies the impossibility of predicting a sign's occurrence from a preceding sign; at the other extreme lie systems with a completely predictable sequence, such as the alternation of red and green at an automatic traffic signal. A sign system like human language is vastly more intricate than these models because of two groups of factors: the interde-

rugged opponent of tradition who became Senior's lifelong friend and exerted considerable influence on him. Senior entered Lincoln's Inn in 1813 to read for the bar; in 1817 he became a certified conveyancer and was called to the bar two years later. Although he earned his living by the practice of his profession, the law was by no means his only interest.

Senior's childhood and youth had been spent in his father's country parish, which meant that early in his life he had become familiar with the poverty and pauperization of agricultural laborers that had occurred during the Napoleonic wars. This experience made a deep impression on him and was undoubtedly one of the reasons for his enduring interest in economics. In 1823 he became a member of the Political Economy Club, to which he was introduced by James Mill; he was active there in discussions with his fellow economists. Shortly after, in 1825, he became the first holder of the Drummond professorship of political economy at Oxford. During his five-year term he published a number of important short works on economics, starting with an analysis of ambiguous economic terms that was published as an appendix to Whateley's *Elements of Logic* (Senior 1826). He published some of his lectures, on such subjects as methodology (1827), the theory of money and international trade (1830a), and population and wages (1829; 1830b). These lectures, together with the others given during his first term in the Drummond chair, were assembled and published as *An Outline of the Science of Political Economy* in 1836. As soon as they appeared, they established Senior's reputation as an economist.

### Role in Whig public policy

By 1830 Senior was well known to leading Whig politicians; he was invited by Lord Melbourne to investigate the laws relating to trade combinations, and Lord Howick suggested he examine the problems of Ireland. His memorandum on trade combinations was not published, but that on Ireland appeared in 1831 as *A Letter to Lord Howick: On a Legal Provision for the Irish Poor, Commutation of Tithes, and a Provision for the Irish Roman Catholic Clergy*. In this pamphlet he advocated the transfer of some of the property of the Anglican church to the Roman Catholic church in Ireland, and as a consequence he was forced to resign the chair of political economy at King's College, London, to which he had only quite recently been appointed.

For the next ten years Senior was constantly engaged in public affairs. He was chief adviser to the Whig party on economic problems, although

his advice was by no means always followed. A pamphlet he wrote in 1835 *On National Property and on the Prospects of the Present Administration and Their Successors*, can be regarded as an unofficial manifesto of the more advanced Whigs: it urged, *inter alia*, the reform of municipal corporations and the admission of dissenters to universities, and again recommended the transfer of some property of the Anglican church to the Roman Catholic church in Ireland. Senior was also a member of several commissions: the Poor Law Inquiry Commission, in 1833; the commission that investigated factory conditions, in 1837; the Royal Commission on the Distress of the Hand-loom Weavers, in 1841; and later, in 1857, the Royal Commission on Popular Education. Each time he was a member of a commission he wrote a substantial part of the commission's report. In his work for the Poor Law Commission, which won great praise, one of his closest collaborators was Edwin Chadwick.

With the fall of the Whig administration in 1841, Senior returned to more theoretical economics. In 1847 he was appointed to the Drummond chair of political economy at Oxford for a second five-year term. His intention of organizing his ideas into a treatise on political economy during these years was not to be fulfilled. Only a few of the lectures were published (1847; 1852), but a large part of the unpublished lectures of this period survive in manuscript. They are remarkable for their attack on the hypothetical economic man of Ricardo's imagination (Bowley 1937).

In the later years of his life Senior was a keen traveler, he was particularly interested in the revolutionary disturbances of 1848 in France and Italy, where he had numerous friends among the liberals. He also visited Greece, Turkey, Egypt, and Malta. He kept journals of these visits and of those to Ireland, some of which were subsequently published.

Senior's wide circle of friends included most of the leading Whigs of his day as well as such intellectuals and writers as Lord Jeffrey, Sidney Herbert, Macaulay, and Thackeray. Among the "philosophical radicals," his closest friends were the Austins and Grotes and, among men with whom he worked, Sir George Cornewall Lewis, Lord Howick, Chadwick, Sir James Stephen, and, of course, Archbishop Whateley. He knew well such French liberals as Alexis de Tocqueville, Guizot, and Faucher, and in Italy he was much appreciated by Cavour.

Senior was a Whig rather than a philosophical radical, but his conviction that man has a natural tendency to improve himself, provided unwise institutions do not discourage him, may well have

developed from his association with the disciples of Bentham. It was this view that led to his controversy with Malthus. Senior's proposals for poor-law reform included the abolition of outdoor relief to the able-bodied, for he believed this sapped the virtues of thrift and independence and also depressed wages. However, he hoped the destitute sick, the aged, and children would be looked after out of public funds in hospitals, almshouses, and orphanages, *not* in mixed workhouses. In general, he believed that the government had a duty to intervene whenever it could do good: expediency should determine the occasions, not a priori rules.

### Contribution to economic theory

During his life Senior's activity in the sphere of social and economic reform was more visible than his work on economic theory. His contribution to the latter, however, was considerable. In contrast to his younger and more famous contemporary, J. S. Mill, Senior's approach to Ricardian theory was essentially critical. His analysis of definitions in the appendix to Whateley's *Logic* (1826) shows how important precision in definition was to him. Concern with rigorous definition led him to make significant changes in the theory of value. Jevons was greatly impressed with this work and considered that he had anticipated the theory of marginal utility in important respects. Senior was clearly influenced by J. B. Say, and in connection with the analysis of degrees of competition in relation to value, he was also influenced by Samuel Bailey.

Senior was less successful with the theory of wages than with the theory of value. He realized that the wages-fund theorem was incomplete, since the determinants of the size of the fund had not been explained, but despite much effort he was unable to solve this difficulty.

His best-known contribution to economic analysis is his abstinence theory of capital. It emerged from his attempt to find a definition of capital that would make capital coordinate with labor in the explanation of the influence of real costs on value; this was an important step in the process of separating the labor theory of value from orthodox economics. The theory stated in his *Outline of the Science of Political Economy* (1836) became an integral part of English capital theory. It was accepted by Marshall as well as by Jevons; the former, however, substituted the neutral term "waiting" for "abstinence." The theory also influenced Continental and American economics.

In the *Outline*, Senior fully accepted Ricardo's theory of land rent while observing that the laws of increasing and diminishing returns are not logically symmetrical. He generalized the analysis to

cover all cases of factors in fixed supply, including natural abilities, and hinted at the concept of quasi rent. This resulted in difficulties in the identification of factor incomes and the relation of rents to costs. Influenced by the German economist Hermann's review of the *Outline*, Senior attacked the problem again in the 1847-1852 lectures. He accepted Hermann's view that land and capital are species of the same genus, arguing that they are indistinguishable in practice and that the distinguishing attribute of land is not its scarcity but its immobility (Bowley 1937).

These theoretical developments necessarily affected the treatment of capital. In the later lectures capital was defined as "any wealth destined to be used productively," including land. This productive use, i.e., capital accumulation, requires "abstinence" as well as the gifts of nature and industry. Abstinence was explained as "the conduct of a person who either abstains from the unproductive use of what he can command or designedly prefers the production of remote to that of immediate results." Frugality, Senior explained, is the "mere refraining from the use of a commodity," but "providence" is "the employment of labour to produce remote results" (quoted in Bowley 1937, pp. 160-161). It must be observed that Senior's distinction between frugality and providence, although apparently similar to the Keynesian distinction between saving and investment, was not made for the purpose of analyzing the level of economic activity.

Senior's contributions to the theory of money and international trade are of less interest today than his other analytical work, but they provided a number of useful clarifications and qualifications to the theory of his time. The discussions of scope and method were contained in various published lectures given at the time of his first and second Drummond professorships and in his *Outline*. His views developed considerably during his life, and the *Four Introductory Lectures on Political Economy* (1852) are a valuable contribution to the nineteenth-century literature on the subject.

MARIAN BOWLEY

[For the historical context of Senior's work, see the biographies of MALTHUS; RICARDO; SAY; for discussion of the subsequent development of his ideas, see the biographies of JEVONS; MARSHALL.]

### WORKS BY SENIOR

- 1821 Essay on the Application of Capital to Land, With Observations Showing the Impolicy of Any Great Restriction of the Importation of Corn, and That the Bounty of 1680 Did Not Lower the Price of It, by a Fellow of University College, Oxford. *Quarterly Review* 25:467-504. → Published anonymously.

- (1826) 1951 *Appendix: On Certain Terms Which Are Peculiarly Liable to Be Used Ambiguously in Political Economy*. Pages 227-239 in Nassau W. Senior, *An Outline of the Science of Political Economy*. New York: Kelley. → First published as an Appendix to Richard Whately's *Elements of Logic*.

## SENSES

- I. OVERVIEW  
II. CENTRAL MECHANISMS

F. A. Mote  
Ragnar Grant

I  
OVERVIEW

In any consideration of behavior it is important to have knowledge of the senses, for the first step in an organism's adjustment to its environment is sensory stimulation. The behavior of primitive organisms is simple and limited; this is so partly because their receiving mechanisms are of such a nature and so structured that the organisms can sense only gross changes in their restricted environment. Higher forms of life have more numerous, more complex, and more sensitive mechanisms; therefore, it is possible for them to react to more environmental changes as well as to changes of wider range and greater subtlety. At the human level the mechanisms have become so specialized, and the environment is so complex, that to understand much of man's most significant behavior, it is necessary to know about the receptor systems by which he senses and adjusts to his varied and changing world.

## Classification of senses

Although it is popularly believed there are only five senses, there are actually more. No specific number can be stated because it will vary from one listing to another, depending upon the criteria used to classify the senses. A set of criteria often used consists of the kind of subjective experience involved—visual, olfactory, tactile, etc.—the type of stimulus, and the sense organ, or receptor. Table 1 outlines this scheme.

## The nature of sensory experiences

The stimulation of a sense organ results in a unique kind of experience, and the differences in kind are what we identify in speaking of auditory, taste, and other types of sensations. The traditional five senses of sight, hearing, taste, smell, and touch have been defined this way since the time of Aristotle, but it has long been known that these do not make the complete list, since sensations of warmth, cold, heat, and pain—in addition to

**Table 1 — Scheme for classifying senses**

Subjective experience	Stimulus	Receptor
Vision	Electromagnetic radiations	Rods and cones of the retina
Hearing	Pressure of sound waves	Hair cells of the organ of Corti of the inner ear
Taste	Various substances in solution	Taste cells in taste buds of the tongue
Smell	Various vaporized materials	Bipolar neurons of olfactory nerve in olfactory epithelium in upper nasal cavity
Touch	Deformation of skin, mucous membrane, internal organs, etc., by stretching, pulling, and similar stimulation	Free nerve endings
Pressure ("deep," i.e., subcutaneous and internal pressure)	Pressure in excess of that required for touch, distension of internal organs, etc.	Pacinian corpuscles in subcutaneous tissue and internal organs
Warmth	Contact by stimulus above "physiological zero," radiant heat, elevation of temperature of surrounding medium	Receptor uncertain or disputed
Cold	Contact by stimulus below "physiological zero," lowering of temperature of surrounding medium	Receptor uncertain or disputed
Pain	Various electrical, thermal, mechanical, chemical, and other agents, e.g., electric shock, radiant heat, puncture, some acids, etc.	Free nerve endings
Vestibular (equilibrium, labyrinthine)	Linear and rotational acceleration, head and body position and movement	Cristae of semicircular canals and otoliths of macula of utricle and sacule (all parts of nonauditory portion of inner ear)
Kinesthesia (movement and "muscle sense")	Movement of muscles, tendons, and joints	Various receptors in muscles, tendons, and joints, e.g., spray-type nerve endings and free nerve endings in muscular tissue and joints, Golgi tendon organs, modified Pacinian corpuscles

touch—can be aroused when the skin is stimulated. Even when these are included, the list is still far too short because movement, pressure, fatigue, nausea, and many others that could be named are experienced as sensations just as much as, let us say, taste and sight. In addition to the differences in kind of sensation from one sense to another, there are also differences in quality within each sense. Not only is taste as a class of sensations different from sight, but the taste quality of sweetness is different from that of sourness, and the visual quality of whiteness different from that of other colors. The number of sensations and their variations and combinations is infinite. To order the domain of the sensations, Hermann von Helmholtz introduced the concept of modality, which is defined as the class of sensations, all of which are alike.

**Intensity.** The basic aspects of sensation are intensity, sensory modality, and sensory quality. First, let us briefly consider sensation intensity. Most sense organs are specialized; that is, they are composed of receptor elements whose threshold of excitability is lower for one form of energy than for any other. This particular type of energy is known as the adequate stimulus. Receptors will react to other stimuli—for example, the application of an electric current or pressure on the eyeball will arouse visual sensations—but the energy required is greater; such stimuli are often referred to as inadequate.

**Absolute threshold.** The minimum amount of the adequate stimulus necessary to excite a sense organ is called the absolute threshold. For some senses the energy required is extremely small; for instance, at the absolute threshold for human vi-

sion the rods can respond when they absorb only 6–10 light quanta, and it has been calculated that movements of the eardrum of the order of  $10^{-2}$  cm. can excite the auditory system.

**Differential threshold.** The senses, however, do more than detect the presence or absence of stimulation; they respond to differences in stimulus magnitude. As the value of the stimulus is increased above the absolute threshold, the sensation experienced becomes more intense—the light becomes brighter and the sound louder. But it is also important to know how much difference there must be so that one light can be seen as brighter than another or what change in sound frequency is required in order to be able to recognize that two tones differ. This is the problem of the differential threshold, defined as the just noticeable difference in stimulation. The size of the differential threshold is a measure of receptor sensitivity; when the just noticeable difference is small, sensitivity is high, when this difference is large, sensitivity is low.

**Work of Weber and Fechner.** E. H. Weber's research in the 1830s and 1840s led him to conclude that the just noticeable difference in stimulus intensities,  $\Delta I$ , depends upon the ratio of their magnitudes, that is,  $\Delta I = I_1/I_2$ , and that for a given class of stimuli the ratio is constant. Thus, if a light intensity of 11 units can be discriminated as just noticeably brighter than one of 10 units, then a light intensity must be of 110 units to be discriminated from one of 100 units, and so on—the constant ratio being  $1/10$  in this example. Although he knew the value of the ratio varied from one class of stimuli to another, Weber believed it was constant for any given class, a generalization that has usually been found to hold true for only a part of the total range of magnitude for any stimulus class. Gustav Fechner applied Weber's findings about intensities of stimuli to intensities of sensation, assuming that a just noticeable increase in stimulus intensity meant there was a constant increment in sensation intensity. He believed the quantitative relationship between stimulus and sensation was logarithmic, and in 1860 he expressed this in his famous psychophysical law:  $S = k \log I$ , where  $S$  is sensation intensity and  $I$  is stimulus intensity (Boring 1942). [A more detailed treatment of thresholds, the relationship between stimulus magnitude and sensation intensity, and the problems and methods involved in their measurement will be found in *PSYCHOPHYSICS*; see also the biographies of *FECHNER* and *WEBER*, *ERNST HEINRICH*.]

**Sensory modalities.** Although the importance of sensation intensity has always been recognized, most of the interest in the senses has centered

about the problems of sensory modality and the quality differences within a modality. Our daily experiences seem to provide the answer to the question "What is there about the stimulus, the sense organ, or the nervous system that explains sensory modality?" To common sense it appears self-evident that, although the nervous system transmits neural activity to the brain, where sensory experience occurs, the essential factor that accounts for sensory modality is the stimulus-sense organ relationship. This determines which experience takes place in the brain. Thus, the color of the grass stimulates the eye, and we have the sensation of greenness; the singing of the bird falls on the ear, and we hear; the skin senses the warmth of the sunshine and the cool of the shade. In order to experience a particular sensation, it is simply a matter of the natural stimulus exciting the appropriate sense organ.

However, it is not only the "natural" stimulus that can arouse a given sensation. For example, a blow on the head will evoke visual sensations and make the ears ring; the usual stimulus for dizziness is spinning or rotating the body, but rotating the visual field will have the same effect; a very warm stimulus may be felt as cold when applied to a cold-sensitive spot on the skin—the "paradoxical cold" phenomenon. These examples demonstrate an important fact: no matter how it is excited, whenever a specific sense organ is stimulated, the sensation is always the same. Yet it is not necessary for the sense organ itself to be stimulated in order for its appropriate modality of sensation to be experienced. For instance, when the optic nerve is cut, a flash of light is seen, and after amputation of an arm there may be reports of touch, itching, pain, and other sensations that are felt as coming from the missing hand and fingers. [See *BODY IMAGE*.]

**Doctrine of specific nerve energies.** If neither a particular stimulus nor stimulation of a particular sense organ is essential, then there must be something about the nervous system that is the necessary factor determining sensory modality. It is this conclusion that Johannes Müller stated in his doctrine, or law, of specific nerve energies (Boring 1942). It was Müller's hypothesis that each sensory nerve has its unique "energy," or quality. Müller's hypothesis declares that sound is sensed because of the unique specific energy of the auditory nerve, smell because of the specific energy of the olfactory nerve, and the other sense modalities because of similar specific energies—and the modalities differ because the specific nerve energies are different. Although no property of sensory nerves has ever been found which supports the specific-energy

concept, Müller's doctrine has been very influential in theory and research upon the senses. It led investigators to look for specialized receptors which, when they activate their sensory nerve, arouse a particular type of sensation [see MÜLLER, JOHANNES].

*Problem of special receptors.* For most of the senses an interrelationship can be found which involves an adequate stimulus, a specialized receptor, and a specific modality of sensation. Light stimulates the rods and cones of the retina, and we see; substances stimulate the taste buds of the tongue, and we taste. Relations of this sort can be found for many modalities. However, such information about some senses is uncertain, and our knowledge of how sensations evoked by stimulation of the skin are mediated is an example of this. The skin is not uniformly sensitive but has "spots" of sensitivity that respond to touch, temperature, etc. Under most conditions no temperature is felt at a given cutaneous region; it is at "physiological zero." Upon being stimulated point by point by a stimulus above this zero value, warmth is not felt at all points nor is cold when a stimulus below this value is used; warm and cold sensations are only reported upon stimulation at certain spots, and the number and location of these are different for the two kinds of stimuli. This finding has been interpreted as indicating the existence of a special receptor for warmth and a different one for cold at each temperature-sensitive spot. A similar interpretation has been proposed for touch, one type of receptor to serve for hairy skin and another type for hairless. Because of their number and nearness to pain-sensitive spots, the free nerve endings are considered to mediate pain. Although the free nerve endings usually are not considered to be specialized receptors, when they are appropriately stimulated, touch and temperature will also be sensed (Weddell 1955).

The cutaneous senses have sometimes been discussed in terms of a conception of modality which implicitly assumes there must be four morphologically distinct types of receptors. But the fact that all the cutaneous modalities can be evoked by stimulating the free nerve endings casts doubt upon the necessity to assume distinct receptor types. The meaning of cutaneous sensation also requires clarification. "Touch," "warmth," "cold," and "pain" do not designate unique sensations perceived in isolation; such terms refer to the predominant experience aroused by particular stimuli. A stimulus above physiological zero applied to the skin evokes warmth as the primary feeling, but the stimulus is also felt as a touch at a particular location, and it is perceived as having temporal and spatial charac-

teristics. This example also illustrates an important phenomenon, that of sensory interaction. The inputs from sensory systems interact at the higher nervous centers and are integrated there so as to give us our perceptions of the environment. [See SKIN SENSES AND KINESTHESIS.]

*Sensation quality.* To speak of sensation is also to speak of sensation quality; the two are inseparable. Visual sensations are white, or gray, or red, or yellow; a pain is "dull," or "aching," or "throbbing"; and similarly for all the senses. The usual method of investigating sensory quality has been to search for the aspects of the stimulus which correlate with quality and variations in quality. For many of the senses some of the most important correlations are known and the factors involved have been studied for many years. For vision the wave length of the light and color quality are correlated; sound frequency correlates with pitch, and the pattern of overtones with the characteristic timbre of musical instruments and the voice; lightly stroking the skin evokes the touch quality of tickling, and so on. Much of our knowledge about the senses consists of information of this sort, and many of the most important generalizations and theories about the senses, such as the Young-Helmholtz theory of color vision and the place theory of pitch for hearing, are explanations of sensory quality [see HELMHOLTZ].

*Receptor-quality correlations.* Obviously, before there can be any satisfactory scientific understanding, the receptor and the quality that are involved in the stimulus-quality correlation must be known. For some senses our knowledge about one or the other of these is questionable. In the case of thermal sensitivity the stimulation is temperature above or below physiological zero, and the sensory quality is warmth or cold, but since there is uncertainty about how thermal sensitivity is mediated, little that is conclusive can be said about any correlation. In the case of olfaction there is the opposite difficulty; here there is no question about the receptor, but anywhere from three to nine classes of odor qualities have been proposed. Since agreement has not been reached about the analysis of the qualities, here too no satisfactory stimulus-quality correlation can be established.

*Localization in the brain.* When it became clear that Müller's specific nerve-energy concept was not tenable, the only reasonable alternative hypothesis seemed to be one which he had considered as a possibility, namely, that when a sense organ is stimulated, its sensory nerve sets up excitation in a particular region in the brain; there is specificity because nerves from different sense organs go to different regions. Specificity does exist in the sense

that the optic-nerve radiations terminate in the occipital lobe of the brain, and hence this is the visual center; the auditory nerve ends in the temporal region, and this is the auditory center, and so on. However, although occasionally someone has entertained the possibility of something like them, no "green center," "warm center," or "center" for sweet tastes or flowery odors and the like has been found. Such a conception of specificity is too simple. [See NERVOUS SYSTEM, *article on* STRUCTURE AND FUNCTION OF THE BRAIN.]

### Methods and findings

Within this century the most significant contributions to the understanding of the senses have come from electrophysiological investigations. By appropriate techniques the responses of individual receptors and of single nerve fibers can be studied as the stimuli are varied. Under most conditions of stimulation the electrical changes recorded from a single nerve unit are a series of discharges, all of the same size, and the unit is therefore said to show all-or-none response. As intensity of stimulation is increased or decreased, it is not the magnitude of discharge of the nerve that varies, but its frequency; and when records are taken from several units, it is found that variation in stimulus intensity is also reflected in the number of units responding. The frequency of unit discharge and the number of units excited are considered to be the basic neural correlates of the dimension of sensation intensity.

Recent research on the electrophysiology of taste has provided data and information which show that some of the ways of looking upon sensation and sensation quality must be reconsidered. That the taste cell of the taste bud is the receptor for taste has long been known, and although from time to time different classifications of primary taste qualities have been proposed, it was finally agreed that there are four: sour, salty, sweet, and bitter. Most of the taste buds are found in small elevations on the tongue known as papillae. Individual papillae have been found which respond exclusively to salt, to sour, and to sweet, but most are stimulated by substances which evoke more than one quality. Recordings have been made of the electrical activity of single units of the nerves supplying various animal taste buds when these are being stimulated by weak acids, sodium chloride, sugar, quinine, and other substances that evoke the different primary taste qualities in the human subject. Such records show that most units respond to more than one substance, and from one unit to another there is variation in the degree of response to different substances. For example, one

unit might respond to both hydrochloric acid and sodium chloride, but in a different degree to each; another unit might respond to the same concentration of these, but to another degree for each, and in addition it might respond to quinine. A third unit might, again, respond to both the acid and the salt at the same concentration, and to still a different degree for each, and to sucrose as well. Thus, although many units may respond to stimuli for the primary taste qualities, each may have its own response "spectrum," or characteristic pattern of sensitivity. Such findings do not support a simple view of four basic receptor-cell or nerve-unit types corresponding to the four taste qualities. "Sweet," "sour," etc. are probably best considered as descriptive headings for taste qualities, rather than as terms signifying any sort of entity. It appears then that neither the responses of individual cells nor of single neural units determine taste quality—it is the patterning of sensory nerve activity which provides the basis for taste discrimination (Pfaffmann 1962).

Electrophysiological methods have been used to investigate the individual receptor elements, the nerve pathways, and the cortical centers for all the senses; information that could have been obtained in no other way has been gathered. By such methods new discoveries have been made which show that some of the traditional views and theories about the senses are too simple and inadequate. [See NERVOUS SYSTEM, *article on* ELECTROENCEPHALOGRAPHY.]

In the past the senses were studied for the purpose of explaining sensations and their qualities. Now there is less emphasis on this, and the senses are being studied in and for themselves in order to gain knowledge about their properties and their processes. Work undertaken with this new purpose is not only giving us better knowledge of sensations and qualities but it is also giving us a larger view of the senses and the part they play in the behavior of organisms.

## II CENTRAL MECHANISMS

Physiology had very little precise information concerning central mechanisms of sensation until the advent of the micromethods of modern neurophysiology. The well-known basic facts concerning specific cortical projection areas for vision, hearing, etc., more properly belong to the conceptual sphere of functional anatomy and pathology. This article will attempt to make some sense out of the less accessible results dealing with the organization of sensory messages and their transmission as revealed by microtechniques in terms of single fibers and individual cells.

The central mechanisms of sensation come into operation at the first synapse which the neural message encounters on its way from the sense organ. In the eye and the ear, for instance, this synapse is located in the periphery at the base of the receptors themselves. For afferents leading from receptors in the skin, the synapse is found in the spinal cord and in its upper extension, the medulla oblongata. In the eye the message is twice reorganized before it reaches the optic nerve, at the synapse of the receptor and bipolar cells and at the synapse of the bipolar and ganglion cells. There, some "sharpening" of the information takes place, aided as we shall see, by the mobility of the eye. Skin and muscular afferents are synaptically connected in the spinal cord to elaborate reflex systems that in turn are controlled by internuncial cells (interneurons) run by centripetal circuits that can redirect, inhibit, or facilitate the passage of information.

The sense organs whose central mechanisms have been most carefully studied are the eye, the ear, and the muscle spindles. These will be used to illustrate some of the leading principles that have emerged from such work.

Let us first consider the extremely high sensitivity of the sense organs. If this sensitivity were

always fully utilized and its effect transmitted to the cortex, the higher centers would be at the mercy of an impulse barrage that would depolarize their neurons to a level fatal for organized life. Obviously situations exist in which full sensitivity is needed, as in extreme twilight vision for the eye, or in the minute adjustments of muscle length made by the spindle organs. But the eye must also be able to function in brightest sunlight, and most muscular movements are coarse and would be disturbed by excessive spindle discharges, which as we know, are returned reflexively to the muscles in which these organs are situated. These two examples suffice to show that sensitivity must be regulated. Much of the most important work on central afferent mechanisms has been devoted to the elucidation of both local and distant (or centripetal) controlling mechanisms that act *internally* on the neurons or receptors themselves. These are distinct from well-known *external* mechanisms, such as pupillary reflexes and activities of the stapedius and tensor tympani muscles in the middle ear.

An important restrictive *peripheral* mechanism requiring brief mention is the adaptation of the receptors that is expressed in a reduction of impulse frequency as a function of the length of time of stimulation (Adrian 1928). The so-called light and dark adaptation of the retina is a borderline case: there is a peripheral shift from rod, or scotopic, vision based on rhodopsin to cone, or photopic, vision as the level of illumination increases, but neural mechanisms within the retinal center itself are also deeply engaged in the adaptive adjustments of the sensitivity of the eye. The details of their mode of operation are not as well known as one could desire. Their existence, however, is well established by several workers (summarized in Granit 1962).

**Relays and transmission.** At an earlier time, the different synaptic stations traversed by a message were regarded merely as relays, a loosely defined function quite apart from the complications alluded to above. We realize today that afferent messages from different receptors at a relaying neuron may be mixed in different ways by the manner in which their afferent terminals converge and that controlling mechanisms interfere at each station, either to specify, amplify, or partially or wholly block a message. Nevertheless, there is always some relay function involved, in the sense that even a modified impulse message must be transmitted to the next station with some fidelity as to its "quantity." Since impulse frequency (in addition to the number of active cells) is a most important determinant of quantity or intensity, clearly there must be a mechanism for relaying it

with a good margin of safety. One factor making a relay reasonably reliable is "synaptic density." A relay could be made to transmit with an equal margin of safety without a dense synaptic projection, but in such systems facilitatory or inhibitory controls would be relatively more important in deciding under what circumstances maximum output would be permitted.

At each relay, impulse frequency is translated at the cell membrane into miniature synaptic currents which can be recorded (through microelectrodes introduced into the cell and connected to amplifiers) as miniature potentials (see Eccles 1957; 1964). These indicate depolarization when the input is excitatory and the opposite, or hyperpolarization, when the input is inhibitory. Several sense organs have both inhibitory and excitatory afferents, the classical example being the large spindle afferents with reciprocally connected inhibitory and excitatory terminals to the protagonist and antagonist ventral horn cells, respectively.

In an excitatory relay of substantial synaptic density, the miniature synaptic currents are in one direction, all depolarizing, and hence will produce a graded change, the depolarizing current, often recordable in terms of electrical potential. Eccles (1957; 1964) calls it the postsynaptic excitatory potential. It will be translated into an impulse discharge. Imitating this process by injecting current through the tip of an intracellular electrode, one finds impulse frequency directly proportional to current strength (Granit et al. 1963). At the next relay these impulses will produce an amount of excitatory current dependent upon the frequency of discharge and the synaptic density. Is this process also directly proportional to impulse frequency? Indirect evidence supports this proposition (see below). The relay function of an afferent neuron lying in the path of the message to the cortex thus consists in translating an impulse barrage into depolarizing current and that once again into an impulse barrage and so on alternately at each subsequent station. Since proportionality is maintained, the message can be transmitted without distortion of the relative order of magnitude. The lemniscal path seems to exhibit the simple relay function described (Mountcastle 1961). The proportionality constants relating depolarizing current strength to impulse frequency are known to vary, and thus if they happened to be large, a sensory effect could be stepped up by amplification, if not, the initial frequency of discharge may be reproduced at the end station in its original version.

When more complex functions are considered, the simple picture drawn above of a pure relay

function ceases to be sufficient. Transmission will then be greatly influenced by internuncial cells that "take orders" from elsewhere. A large number of them characteristically fire rapid bursts of impulses when stimulated by a single shock. When tested for their impulse-producing capacity by injected currents, these cells have been proved to possess very large proportionality constants, meaning that very small amounts of current elicit fast frequencies of discharge. Such cells are therefore well suited for "biasing," in the positive or negative direction, the relays upon which they impinge.

**Specific and diffuse afferents.** When a sense organ has to deliver specific information of a more discriminative nature referring to spatial localization or some modality, this information is arranged spatially with considerable precision both at intermediate and at end stations. Topographic differentiation by means of somatotopic afferents is thus a major analytical tool of the physiological organization by which input is differentiated. In vision the physiological maps are particularly precise. The eyes, for instance, are represented by alternate layers in the geniculate body in such a manner as to join corresponding points of the retinal field in identical layers. The information, thus organized, is delivered to a cortical map of great precision. For touch, Woolsey (1952) has worked out detailed cortical charts by the method of evoked potential. Even quality may in some systems be mapped out. This is the case in the cortical area for tonal representation (Tunturi 1950). Examples could be multiplied to show how information on the structure of bodily space is charted in this manner by localized signals.

Differentiation by the basic principle of maintaining the topography of sensory impulses from sense organ to cortex is, however, not the only afferent mechanism known. There are also cells which serve diffuse or nonspecific functions. This concept is not easy to define with precision. Perhaps the best way of defining a diffuse afferent system is to call it "a system of cells on each of which afferent fibers of several modalities converge," or if the afferents be of one modality, "cells receiving projections from an extensive section or area of the body." Magoun's (1950) concept of the ascending reticular system is of the former type, in which neurons in the brain stem receive terminals from afferents representing a large number of different modalities, as proved in unit analysis by Moruzzi and his co-workers (Scheibel et al. 1955). Of the other type is the spinothalamic system, whose thalamic neurons have receptive fields which may include one half or the whole of the

body (Mountcastle 1961). They may, however, have terminals from two modalities (if pain be a modality) because nociceptive stimuli also discharge the cells which are sensitive to mechanical stimulation of the skin. In the retina the giant ganglion cells have branches that collect information across an area with a diameter of maximally 1 mm., representing several hundred thousand receptors, both rods and cones. Within the tactile system of the gracilis nucleus of the dorsal-column afferents, there are separate cells for localized messages and for highly convergent information coming from a large area.

What function should be assigned to diffuse systems? Only a partial answer can be given. For the reticular activating system, Starzl, Taylor, and Magoun (1951) suggest (as does the name itself) that it plays the role of keeping the brain alert and active, since somnolence occurs when this portion of the brain stem is removed. Granit (1955), drawing attention to the widespread spontaneous activity of nerve cells, has made two suggestions: (1) that the diffuse sensory input serves an energizing function; that is, it maintains some basic depolarization by random impulses which is necessary for the upkeep of spontaneous activity in the higher centers; and (2) that spontaneous activity in its turn is necessary as a background for the central recognition of inhibition. As we shall see below, inhibition is necessary in discrimination, but it needs a background of central excitation in order to be "informative." In studying intracellularly the afferent input from stretch receptors, we have been able to demonstrate (Granit et al. 1964) that, unless the cell (a motoneuron) is depolarized to some extent, both inhibitory and excitatory effects of stretch tend to be dissipated as sheer noise consisting of miniature potentials at the cell membrane, while in slightly depolarized cells, excitations really excite and inhibitions really inhibit.

The final cell. The neurophysiologist whose understanding depends on interpreting "spikes" (impulses) or membrane events (synaptic activation noise, membrane potential) has no experimentally based philosophy as to which, if any, of his indices comes close to the conceptual world of psychology. So far he has done best on spikes and has been tacitly inclined to imagine that unless a cortical cell delivers spikes, it is of but modest interest in the nervous machinery designed for discrimination of one message from another. Yet, while he is recording from the "final cell" in a cortical layer, no neurophysiologist is likely to believe that he is doing anything more than sampling one link in an organization of cortical cells that, ac-

cording to the anatomist Ramón y Cajal (1923), consists of a "cortical sector" (a "cone" would have been a more appropriate term) with its top downwards. Within this sector the cells are linked vertically. Physiological research (see below) has recently been able to make valuable use of Ramón's concept.

The role of inhibition. Impulse recording made it possible for the first time to assign definite tasks to nervous inhibition in the elaboration of the sensory message. Previously, central inhibition had been measurable only in reflex work, using muscular contraction or secretion as indices. Graded excitation (depolarizing current) has its equivalent antagonist in graded inhibition (hyperpolarizing current), often recordable by the intracellular technique as the "inhibitory postsynaptic potential" (Eccles 1957; 1964). However, most information of interest for the present theme has been obtained in terms of a reduction of impulse frequency.

Inhibition within a sensory system achieved functional prominence in the vertebrate retina for the first time when it was shown that the off-discharge at cessation of illumination was preceded by inhibition and easily inhibited by reillumination (Granit & Therman 1935; Hartline 1938). The retina is our most highly developed sense organ, and if natural stimulation of it by light could stop a discharge as well as start it, then surely inhibition is of first importance. The on-off pattern of discharge delivered by the individual optic nerve fibers was later also seen in the auditory system (Bremer 1943). However, in vision its significance is far better understood, apparently because the spatial element of the organ of sight is more accessible to analysis. From the beginning it was held that the on-off units of the retina would blaze the trail of a moving object with a recognizable spike pattern and that, similarly, contours would be emphasized because both regular and small, irregular eye movements light it up with on-off spikes. It has since been shown in precise experiments (Ditchburn 1955) that if the image on the human retina is maintained stationary by appropriate optical arrangements compensating for slight, unavoidable eye movements, then it also tends to fade out.

The on-off element, and likewise a smaller number of pure "on" and pure "off" elements, represents a receptive field of convergence together with an analyzer residing in the nervous structure between receptors and the ganglion cell whose message is recorded. The size and organization of the receptive field were first studied, with the aid of small spots of light, by Hartline (1940) in the frog and

then in the cat (Kuffler 1953), where they were found to be differentiated to the extent that they possess a center that is either "on" or "off." In both cases the surrounding part of the field had the opposite character. In the goldfish the receptive field has also been investigated with respect to wave-length sensitivity, and it has been found that this antagonism between center and periphery with respect to on and off may also be an antagonism in terms of spectral regions of sensitivity. The overlapping mosaic of receptive fields thus forms a dynamic interaction pattern which, transmitted up the optic nerve, can do justice to the infinite variety of form, movement, and color that a moving animal has to interpret and that it ultimately reproduces in the form of a stable world of sight. In this act inhibition is just as vital as excitation.

**Recurrent inhibition.** Recurrent inhibition is another significant and apparently common process in the organization of the sensory (and motor) message because it rejects unwanted components, emphasizes differences of "quantity" within a complex message, and apparently also stabilizes a steady discharge. Its basis is the common occurrence in all centers of recurrent collateral fibers returning directly or across an interneuron to the cell or cell system from which the parent fiber emerged. Most of our knowledge of this process, inasmuch as it consists of precise measurements, derives from cells as different as vertebrate ventral horn cells and the horseshoe crab (*Limulus*) ommatidia. In the latter case (Hartline & Ratliff 1958) the afferent large axon from each ommatidium sends fibers with inhibitory axo-axonic synapses to adjacent axons. Assume that an image is focused onto some ommatidia with irradiated light unavoidably spreading across surrounding ones. The ommatidia in focus will fire at higher frequencies than those in the surrounds. The recurrent inhibition has proved to be proportional to impulse frequency and hence the focal cells will inhibit those in the neighborhood more than the latter can inhibit them. As a consequence the image will be sharpened by "contrast."

Nature has preserved, as it were, the idea of recurrent, or "lateral," inhibition (in Hartline's terminology) through countless ages of phylogenetic development; recurrent fibers are found in most centers, both motor and sensory. In the ventral horn cells (Granit & Renkin 1961), in addition to "motor contrast," a stabilizing effect on the discharge frequency in tonically active cells can be demonstrated. While in the *Limulus* the mechanism appears to be wholly automatic, in the ventral horn cells it is provided with an internuncial neu-

ron, the so-called Renshaw cell, and hence is facultative (for a summary, see Granit 1963).

These cases of recurrent inhibition are the only ones analyzed in detail, but further developments can be expected, since qualitative work has already been done, for instance, in the hippocampus, in the olfactory bulb, and in the gracilis nucleus.

Lateral inhibitory effects delimiting the area stimulated have also been described under the heading "surround" or "afferent inhibition" by Mountcastle (1957) and his co-workers. Thus Powell and Mountcastle (1959), recording from the somatic cortical area of the macaque monkey, have found skin fields in which a central nucleus of excitation to touch was surrounded by an inhibitory zone. The mechanism in this case may well be recurrent inhibition improving at each relay definition of locality.

Inhibition also apparently plays a decisive role in sharpening up information about quality. In some optic nerve fibers the spectral response in terms of threshold sensitivity appears restricted to, say, the red, green, or blue wave lengths. This is the so-called modulator type of response. The dominator type of response is sensitive across the spectrum. The modulator bands are now generally held to be caused by inhibition sharpening up color specification. Broad and narrow bands of spectral sensitivity have also been recorded from higher visual stations. A recent discussion of the neural mechanisms specifying wave length has been given by Granit (1962). As to specification of tonal quality, Galambos (1954) points out that inhibition in this system also restricts the originally broad sensitivity of the peripheral acoustic mechanism to a narrow band, a process that is likely to take place already within the cochlea. Tonal bands of different width, also depending upon the frequency range which the nerve fibers carry, are thus delivered to both the visual and the auditory cortical area.

**Centrifugal control.** The sense organ in which centrifugal control is best understood is the muscle spindle; this organ is located within a spindle of thin muscles (so-called intrafusal muscle fibers) that are provided with special efferent fibers that can be stimulated both artificially and across natural reflex or supraspinal connections. Under such circumstances the intrafusal muscle fibers contract and thereby stretch the sensory spindle endings, which respond by discharging afferent impulses. There is a large literature in this field (Leksell 1945; Granit 1955) which cannot be reviewed here. Relevant in this connection is the principle of centripetal determination of the level of sen-

sitivity in terms of spindle length. This is of fundamental importance because from the spindle the afferent impulses run to ventral horn cells, setting up efferent impulses to—among others—the large muscles in which the spindles are located; these muscles in turn are forced to contract until the tension on the sense organ is relieved. Thus, the length at which the muscle operates is determined by centrifugal control of spindle length, an interesting case of a centrally controlled sense organ which at the same time is a motor organ.

There is also a considerable literature on the olivo-cochlear Rasmussen bundle of efferent fibers, which exert a direct inhibitory effect that can be recorded both in auditory single fibers and at the cochlea. Both crossed and uncrossed olivo-cochlear fibers exert inhibitory effects, but their significance cannot yet be said to be fully understood. A possibility is that they play a role in binaural localization. (For the relevant literature see Galambos 1956; Fex 1963.)

The retina is likewise provided with centrifugal fibers, which is hardly surprising because it is a true nervous center in spite of its peripheral localization, and as pointed out above, centripetal control of nervous centers is common. The scant literature in this field has been summarized by Granit (1962).

**Cortical analysis.** At the level of detail alluded to in this brief review, analyses are restricted to the study of the organ of sight (see Hubel & Wiesel 1959; 1963; Jung & Kornhuber 1961). Hubel and Wiesel have made a thorough investigation of the receptive fields of cortical cells stimulating the eye (of a cat) by small visual objects influencing the firing of single cortical units. The receptive fields in the cortex were found to be organized either with excitatory on- or inhibitory off-centers in the middle, the surrounds being of opposite character (see above for similarly organized retinal receptive fields). The cortical receptive fields are more elongated than the retinal ones, and they are oriented in different directions. The antagonism between center and periphery of the cortical receptive field makes stimuli covering the whole field or diffuse illumination relatively ineffective. The same properties make these fields extremely sensitive to form, size, position, and orientation of the stimulus and likewise sensitive to directional movement of a spot of light across the retina; this is easily understood, considering that a moving spot can traverse elongated fields in different directions. Some units were binocular, others monocular.

Recalling that Powell and Mountcastle (1959) had found that tactile cortical regions are columnar in shape with similar responses to a microelectrode which apparently penetrates one of Ramón's sectors (see above) from above downward, Hubel and Wiesel (1963) made an analysis of receptive visual fields in a similar manner. They found a number of columns in the visual area in which receptive-field orientation was maintained, suggesting that columns of ordered sequences of field orientation are actually part of the central sensory mechanism, defined, of course, in functional terms.

## SENSORY AND MOTOR DEVELOPMENT

Sensory and motor functions are basic to all behavior. In its simplest form, the stimulus-response unit of behavior is composed of a receptor (sense organ), neural impulses traveling over afferent, central, and efferent pathways, and some resultant form of motor (muscular) response. The sense organs respond selectively to various stimuli (visual, auditory, olfactory, thermal, tactual, proprioceptive, chemical, and gravitational), and the resulting responses most often involve some form of muscular reaction appropriate to the nature of the stimuli received. Developmentally, the earliest forms of behavior are simple sensorimotor reflexes. With growth, maturation, and differentiation, the senses become more acute, and the muscles become stronger and function more smoothly. At the same time, the central nervous system matures, with its increasingly meaningful accompanying sensory perceptions, and the motor responses become better organized, while many of the reflexes give way to behaviors under voluntary control.

During the period of earliest development, when the changes are most rapid, there is a close coordination between structure and function. Gradually the functions become relatively independent of the structures. As the rate of growth slows, the structures differentiate, and the functional processes become increasingly complex; that is, once the basic structures are formed, there is little or no correlation between their normal variations in structural complexity or maturity and the increasing complexity and diversification of motor coordinations, perceptions, and other mental processes.

Neural and cortical development. Conel's studies of the postnatal development of the human cerebral cortex (1939-1963) have been well summarized by Eichorn (1963) and by Eichorn and Jones (1958), who also point out that changes in the histologic structure coincide with developmental changes in neural function as expressed in the electroencephalogram. At birth and even at one month the cortex is very immature, with fragile cell processes, no Nissl bodies, and very few neurofibrils. The greatest cortical development occurs

in the primary motor area of the upper trunk, leg, hand, and head, followed in order by primary somesthetic, visual, rhinencephalon (olfactory), and auditory areas, with other parts still very immature. By three months there are marked advances in the number of nerve fibers, both exogenous and associational, with greatest development in the motor area of the hand, frontal eye fields, and striate cortex (Gruner 1962). There is also over this period a rapid advance in myelination of the neural fibers. This myelination serves to channel the neural impulses along fibers and to reduce random spread of impulses across neurons. Again, at six months there is marked development, particularly in motor areas controlling the hand and upper trunk, leg, and head, while visual and somesthetic sensory growth is accelerated. Between 6 and 15 months the motor areas of the brain show less marked growth, with the order of maturity being hand, upper trunk, head, and leg. The primary visual area by now is second to the motor, with the visual association areas more developed than the somesthetic association areas.

Parallel with these histological changes, Eichorn and Jones (1958) point out that at birth the electrical activity of the cortex is very slow and irregular, with the greatest regularity in the region of the most mature cortical structure. It is possible, however, to induce some rhythmic EEG patterns in the neonate and in the month-old infant, while between one and three months there is a shift of the EEG from random activity to some patterned slow activity in the visual and auditory sensory areas of the brain.

**Fetal development.** We find, too, a definite parallel between early behavior and the neural histology and electrical functions in these early months. The very first actions of the fetus, according to Hooker (1943), are muscular: the rhythmic beating of the heart in the third week of gestation. This, however, is a preneural action of the heart muscle. A response (presumably neural) to stimulation was first observed at eight weeks and consisted of a lateral bending of the neck which moved the head away from a hair touching the area of the cheek. Carmichael (1946) has given an excellent account of this early fetal development. He points out the gradual involvement of the entire body and the appearance of reflexes until, by 26 weeks of gestation, the reflexes necessary to life are usually present. These reflexes include functioning of the respiratory, circulatory, and digestive systems as well as the sense organs that respond to light, sound, touch, body position, and so on.

### Sensory development

Because the infant's repertoire of responses is so limited, it is difficult to obtain exact information about sensory acuities. However, it is possible to observe and record such behaviors as visual regard, pupillary reflexes to light, startle, and changes in activity level to sounds and tactile stimulation. More recently, sensory reactivity has been recorded by observing changes in EEG and in heart rate and by such devices as observing eye nystagmus to moving striped patterns (Eichorn 1963; Fantz & Ordy 1959).

It is evident that the intact full-term newborn in some degree sees, hears, and responds to pressure, touch, taste, and change in temperature. There is evidence from his behavior and from the structures of the nervous system that of his various senses, vision is most developed.

**Vision.** Changes in visual acuity during the first month appear to be very slight. As observed in a standard test of infant development, soon after birth the infant will briefly regard a large moving object (such as a person) nearby and directly in his line of vision. A little less often he will regard a small bright red object in motion, when it is held about eight inches above his eyes (Bayley 1933; White, Castle, & Held 1964). At about two weeks his gaze may follow this moving object (a red plastic ring) across his visual field—right to left or the reverse (Bayley 1933). At three weeks his eyes may follow a moving person two or three feet away. At about one month he follows the red ring with up and down eye movements and, a little later, as it is moved slowly in a circle (18 to 24 inches in diameter). At six or seven weeks the infant appears to inspect his surroundings when carried in an upright position, and he turns his eyes toward the red ring at a thirty-degree angle when it is moved into his field of vision from the side. By the fourth month the infant's retina is able to accommodate to objects at varying distances in an almost adult fashion (Haynes, White, & Held 1965).

In experimental situations several investigators have found very early evidences of differentiation of visual stimuli. Several studies have shown (Berlyne 1958; Fantz 1958) that infants three to four months of age indicate preference for (that is, spend more time looking at) patterned stimuli as contrasted with plain ones. Fantz and Ordy (1959) have shown that infants under five days of age will look more at black and white patterns than at plain-colored surfaces. Doris and Cooper (1964,

p. 456) have reported a clear correlation between age and brightness discrimination among 16 infants 4 to 69 days of age. They tested this by observing nystagmic eye movements to a moving field of black and white stripes. [See PERCEPTION, article on PERCEPTUAL DEVELOPMENT; VISION, article on EYE MOVEMENTS.]

These findings are in general agreement with the responses to visual stimulation observed in the infant mental scales. Continuing with the Bayley Scale (Bayley 1933), at around two months the baby blinks at the shadow of a hand passed quickly across his eyes, he visually recognizes his mother, and his eyes follow a moving pencil; at two and one-half months he searches with his eyes for a sound, and he regards a one-inch red cube on a table when he is held upright; at three and one-half months his eyes follow small objects, such as the red ring, a teaspoon, and a ball, as they move across the table before which he is held in a sitting position. A typical four-month-old's occupation is to inspect his own hands; at four and one-half months he regards a pellet one-quarter inch in diameter; at five months he discriminates between strangers and familiar persons (largely visually, it would appear, from the expressive nature of his gaze). This evidence of visual discrimination of patterned objects shows advancement when at twelve months he looks with interest at colored pictures in a book. Many of his behaviors in the second year give evidence of his utilization of visual discriminations as he imitates motions, builds towers of cubes, adjusts round, square, and triangular blocks into their appropriate form-board holes, and goes on to more complex operations.

Increasing visual acuity in the first few months of life for premature and full-term infants has been assessed by Brown (1961).

Another source of information on visual development comes from the studies of ophthalmologists. Keeney (1951) has tabulated functional development of vision and binocularity for a series of ages from the third fetal month to nine years. Many of his items are identical with, or closely similar to, those already noted. We may add sensitivity to light at the seventh fetal month and a series of visual acuity fractions starting at one year, when visual acuity is about 6/60 with imperfect fusion. At two years it is at least 6/12. At two and one-half years more mature mechanisms of accommodation result in improved acuity. At three years vision is about 6/9, at three and one-half years fusion capacity is improving, at four years vision is near 6/6. At five years ocular pursuit is inferior to fixation, and at five and one-half

years fusion is well established and accurate. By six to six and one-half years ocular pursuit is accurate, and the average child can discriminate letters and word symbols and begin to read. Thereafter up to the age of nine, ability to tolerate prism vergences develops and continues to increase. [See VISION.]

Thus, we see that even though vision is present at birth and, relative to the other senses, advanced, acuity in one aspect or another continues to increase, at least up to nine years. The changes are more rapid at first and become slower with advancing age.

The eye is the most highly developed and complex of the sense organs, and we find, accordingly, that the development of visual acuity is a function of several variables, including the simple ones, brightness and hue; patterned vision, which is related to degree of complexity of both qualitative and quantitative variables; and depth discrimination, both monocular and binocular, together with the development of accommodation and convergence. Much remains to be done in clarifying and identifying the developmental aspects of all of these.

In the senses generally, and most acutely in vision, the pure sensory aspects of development are confounded with perception and the meaningful and adaptive responses to the stimuli which are presented for the study of sensory discrimination.

**Hearing.** The developmental pattern of auditory acuity is in many ways similar to that of vision. The normal newborn infant responds, by reflex startling, to a sharp, loud clack or the ringing of a bell near his ear (Bayley 1933). Ten days after birth he reacts to the lesser sound of a rattle and at twenty days to the sound of a softly speaking voice. The localization of the source of a sound is incipient in the two-and-a-half-month-old who may be seen to search with his eyes for the bell or rattle when sounded outside his field of vision. By three months his eyes will turn from the bell to the rattle and back, when they are sounded alternately while held eight inches apart in his field of vision. The four-month-old will turn to the right and the left to see the bell which has been rung opposite first one ear and then the other.

There is evidence of rapid cortical development in the auditory area of the cortex in the first four months. Normal acuity appears to be well developed by this age (Wever 1949). Further changes in hearing appear to be primarily perceptual. The six- to seven-month-old is interested in producing sound. He bangs his hand or a toy on the high-chair and listens. He babbles and repetitiously tries

out syllables. At eight to nine months he listens selectively to familiar words and begins to respond appropriately to simple commands.

Auditory acuity varies according to the pitch of the sound (Wever 1949, p. 364). However, this variation in pitch sensitivity appears to be a function of individual differences rather than development in the infant and child. After thirty years there is some decrement in auditory acuities, and this is greater for increasingly higher pitches (Wever 1949; Sommers, Meyer, & Fenton 1961). [See HEARING.]

**Tactual and pain sensitivity.** There is evidence of increasing sensitivity to pain in the first four days of life (Lipsitt & Levy 1959) and probably for a somewhat longer period of infancy. Schludermann and Zubek (1962) found no changes in pain sensitivity from age 12 through 50, though decrements occurred after that age.

The young infant clearly reacts to tactual stimulation. However, skin sensitivity also appears to increase with age. For example, Ghent (1961) studied tactual thresholds in the hands of children 5 to 11 years old and found that sensitivity increased over this age range. She also found a sex difference, with girls showing greater sensitivity and approaching the adult level of sensitivity at an earlier age. [See PAIN; SKIN SENSES AND KINESTHESIS.]

## Motor development

The development of motor coordinations, evidenced first in simple reflexes, appears to depend on the interactions of muscular response to stimulation, growth and increasing strength of the muscles, and the development of coordination through practice. All of these are interdependent. Practice strengthens the muscles and stimulates their growth. It also promotes learning, for example, through the simultaneous stimulation of visual and muscle senses in the eye-hand coordinations involved in reaching, grasping, and manipulating small objects. In newborn infants these coordinations are seen in such reflex responses as head lifting, various postural adjustments to body position, crawling, and reflex grasping. Soon, between one and two months, we observe playful bursts of activity in the form of arm and leg thrusts. As the muscles grow stronger, the infant is able to hold his head erect, to push his chest up by his arms, to turn from his back to his side at four months, and to sit, at first with support and by six months, alone (momentarily). By three months his hands are no longer tightly fistled, and he holds a small toy with a grasp which is no longer entirely reflex.

The six-month-old will reach for a toy with one hand. (Earlier he tends to "close in on" an object, using both hands simultaneously.) He shows early manual coordination in rotating his wrist, in partially using his thumb in opposition to his fingers, in grasping, and in trying to pick up pea-sized pellets. The eight-month-old sits alone steadily, may be starting to crawl or creep, and picks up small objects with complete thumb opposition. By nine months he can get himself into a sitting position and pull to a standing one by his crib rail. The ten-month-old creeps with agility and can often walk with help, sit down, and bring his hands together for games like pat-a-cake.

The one-year-old can take a few steps alone. In the next six months he will be able to throw a ball, walk backwards, and walk up and down stairs with help. The two-year-old walks up and down the stairs without holding on, and by three years he jumps from small heights, runs, walks on tiptoe. The four-year-old can walk a line and can hop a few steps on one foot.

**Individual variability.** There are of course, large individual differences in the age at which children become able to do these things, as well as differences in the skill and smoothness of motor coordinations. Motor skills after early infancy are very largely determined by practice. Furthermore, there is great specificity in skills. Evidently each motor function must be practiced in order for it to be performed with skill. Ability to catch a ball cannot be used to predict ability at the high jump or the broad jump. Bayley (1951a), for example, found that for ages 4½ to 12 years, scores on a battery of ten tests of manual dexterity were unrelated to strength and showed correlations of about .40 with scores on jumping (sum of three tests) and of .28 with scores on balance (sum of five tests). Scores on jumping, balance, and strength tended to correlate with each other at around .30 for most ages. Similarly, Espenschade (1940) found for children of 13 to 17 years no relation between gross and fine motor skills, though similar gross motor activities were moderately related. For example, scores on the dash usually correlated near .60 with those for the broad jump, near .40 with the jump-and-reach, and near .40 with the distance throw.

**Consistency over time.** Correlations showing the degree to which scores are consistent over time, on total motor tests, are only moderate in young children. For example, in the Berkeley growth study Bayley (1935) found that correlations of scores at 27 and 30 months with scores at six younger age levels in the first two years are, with two exceptions, below .40. At later ages, between

4 and 12 years, these Berkeley children's scores on the manual dexterity tests again show only moderate consistency over time. Scores on the 1½ year test showed correlations of .29 with scores at 4½ years, .50 at 5½ years, .49 at 6½, .55 at 7½, and .49 at 8½ years. Espenshade (1940) gave a series of motor tests to 160 children tested at six-month intervals between the ages of 13 and 17 years. She found a fair degree of consistency over a four-year period for most individual children. Glassow and Kruse (1960) found similar stability in relative scores for girls aged 6 to 14 years, with the running and jumping scores more stable than scores for throwing. Inconsistency in these cases may be attributed to the fact that scores in adolescents tend to be related to the degree of physical maturity and strength.

As measured by scores on standard tests of motor abilities, motor skills are seen to increase continuously through infancy and childhood. The increases are greatest in the first 18 months, after which the rate appears to decelerate gradually (Bayley 1951a).

**Sex differences.** There is no sex difference in motor-test scores during the first 12 years (Bayley 1939). However, after this age the girls' scores tend to stabilize while the boys' scores continue to increase (Espenshade 1947). This continued increase in boys' scores is correlated with their continuing growth in strength (Govatos 1959). Furthermore, both strength and scores in gross motor abilities are correlated in boys with their degree of physical maturation (Jones 1944; Clarke & Harrison 1962). Those who are accelerated in pubertal development are stronger and more skilled in gross motor coordinations than their more slowly maturing age peers. It is also true that the more muscular boys, with strongly masculine physiques, are stronger than those with less masculine builds (Bayley 1951b). [See INDIVIDUAL DIFFERENCES, article on SEX DIFFERENCES.]

**Specificity.** In general, after the first 15 months of age, motor skills evidence much specificity (Bayley 1951b; Espenshade 1947; Lotter 1961). It is evident also that motor skills are very responsive to practice and training (Clarke & Henry 1961; Clarke & Petersen 1961). This appears to be evident even in the very young (Holt 1960). Within normal limits and the limits of muscular strength, it should be possible to increase specific motor skills considerably through practice.

## SEQUENTIAL ANALYSIS

Sequential analysis is the branch of statistics concerned with investigations in which the decision whether or not to stop at any stage depends on the observations previously made. The motivation for most sequential investigations is that when the ends achieved are measured against the costs incurred (including the cost of making observations), sequential designs are typically more efficient than nonsequential designs; some disadvantages of the sequential approach are discussed later.

The term "sequential" is occasionally extended to cover also investigations in which various aspects of the design may be changed according to the observations made. For example, preliminary experience in an experiment may suggest changes in the treatments being compared; in a social survey a small pilot survey may lead to modifications in the design of the main investigation. In this article attention will be restricted mainly to the usual situation in which termination of a single investigation is the point at issue.

In a sequential investigation observations must be examined either one by one as they are collected or at certain stages during collection. A sequential procedure might be desirable for various reasons. The investigator might wish to have an up-to-date record at any stage, either for general information or because the appropriate sample size depends on quantities that he can estimate only from the data themselves. Alternatively, he may have no intrinsic interest in the intermediate results but may be able to achieve economy in sample size by taking them into account. Three examples will illustrate these points:

(1) An investigator may wish to estimate to within 10 per cent the mean weekly expenditure on tobacco per household. In order to determine the sample size he would need an estimate of the variability of the expenditure from household to house-

hold, and this might be obtainable only from the survey itself.

(2) A physician wishing to compare the effects of two drugs in the treatment of some disease may wish to stop the investigation if at some stage a convincing difference can already be demonstrated using the available data.

(3) A manufacturer carrying out inspection of batches of some product may be able to pass most of his batches with little inspection but may carry out further inspection of batches of doubtful quality. A given degree of discrimination between good and bad batches could be achieved in various ways, but a sequential scheme will often be more economical than one in which a sample of constant size is taken from each batch [see QUALITY CONTROL, STATISTICAL for further discussion of such applications].

The most appropriate design and method of analysis of a sequential investigation depend on the purpose of the investigation. The statistical formulation of that purpose may take one of a number of forms, usually either estimation of some quantity to a given degree of precision or testing a hypothesis with given size and given power against a given alternative hypothesis. Economy in number of observations is typically important for sequential design. Some details of particular methods are given in later sections.

Sometimes a sequential investigation, although desirable, may not be practicable. To make effective sequential use of observations they must become available without too great a delay. It would not be possible, for example, to do a sequential analysis of the effect of some social or medical policy if this effect could not be assessed until five years had elapsed. In other situations it may be possible to scrutinize the results as they are obtained, but only at very great cost. An example might be a social survey in which data could be collected rather quickly but in which a full analysis would be long and costly.

**History.** An important precursor of the modern theory of sequential analysis was the work done in 1929 by Dodge and Romig (1929-1941) on double sampling schemes. Their problem was to specify sampling inspection schemes that discriminated between batches of good and bad quality. The first stage of sampling would always be used, but the second stage would be used only if the results of the first were equivocal; furthermore, the size of the second sample and the acceptance criteria might depend on the first stage results. Bartky (1943) generalized this idea in his "multiple sampling," which allowed many stages, and his procedure

was very closely related to a particular case of the general theory of sequential analysis that Wald was developing simultaneously.

This theory, developed for the testing of military equipment during World War II, is summarized in Wald's book *Sequential Analysis* (1947). It represents a powerful exploitation of a single concept, the "sequential probability ratio test," which has provided the basis of most subsequent work. Related work proceeding simultaneously in Great Britain is summarized by Barnard (1946). Whereas Wald's theory provided the specification of a sampling scheme satisfying given requirements, Barnard's work was devoted to the converse problem of examining the properties of a given sequential scheme. Barnard drew attention to the close analogy between sequential inspection schemes and games of chance. Indeed, some of the solutions to gaming problems provided by seventeenth-century and eighteenth-century mathematicians are directly applicable to modern sequential schemes.

Postwar theoretical development, stimulated primarily by Wald's work, has perhaps outrun practical applications. Many recent workers have apparently felt that the standard sequential theory does not provide answers to the right questions, and a number of new lines of approach have been attempted.

**Sequential estimation.** Suppose that in a large population a proportion,  $p$ , of individuals show some characteristic (or are "marked") and that in a random sample of size  $n$  the number of marked individuals is  $X$ . Then the proportion of marked individuals is  $X/n$ . By standard binomial distribution theory, the standard error of  $X/n$  is  $\sqrt{p(1-p)/n}$ . The standard error expressed as a proportion of the true value is therefore  $\sqrt{(1-p)/np}$ , and when  $p$  is small this will be approximately  $(np)^{-1/2}$ . Now  $np$  is the mean value of  $X = n(X/n)$ . Intuitively, therefore, one could achieve an approximately constant proportional standard error by choosing a fixed value of  $X$ . That is, sampling would be continued until a predetermined number of marked individuals had been found. This is called a "stopping rule." The sample size,  $n$ , would be a random variable. If  $p$  happened to be very small,  $n$  would tend to be very large, an increase in  $p$  would tend to cause a decrease in  $n$ . This procedure is called "inverse sampling," and its properties were first examined by Haldane (1945).

At first sight it seems natural to estimate  $p$  by  $X/n$ . This estimator is slightly biased under inverse sampling, and some statisticians would use the modified estimator  $(X-1)/(n-1)$ , which is unbiased. Others feel that  $X/n$  is preferable despite

the bias. In most practical work the difference is negligible.

Inverse sampling is one of the simplest methods of sequential estimation. One could define different stopping rules and for any particular stopping rule examine the way in which the precision of  $X/n$  varied with  $p$ ; conversely, one could specify this relationship and ask what stopping rule would satisfy the requirement.

If a random variable is normally distributed with mean  $\mu$  and variance  $\sigma^2$ , a natural requirement might be to estimate  $\mu$  with a confidence interval of not greater than a given length at a certain probability level. With samples of fixed size, the length of the confidence interval depends on  $\sigma$ , which is typically unknown. The usual Student  $t$  procedure provides intervals of random and unbounded length. Stein (1945) describes a two-sample procedure (with preassigned confidence-interval length) in which the first sample provides an estimate of  $\sigma$ . This estimate then determines the size of the second sample; occasionally a second sample is not needed. This scheme leads naturally to a general approach to sequential estimation. Suppose that, as in inverse sampling, one proceeds in a fully sequential manner, taking one observation at a time, and stops when the desired level of precision is reached. This precision may be determined by customary standard error formulas. Anscombe (1953) showed that in large samples this procedure will indeed yield estimates of the required level of precision. Thus, suppose an investigator wished to estimate the mean number of persons per household in a certain area, with a standard error of 0.1 person, and he had little initial evidence about the variance of household size. He could sample the households until the standard error of the mean, given by the usual formula  $s/\sqrt{n}$ , fell as low as 0.1. A practical difficulty might be that of ensuring that the sampling was random.

**Sequential hypothesis testing.** Suppose that one wishes to test a specific hypothesis,  $H_0$ , in such a way that if  $H_0$  is indeed true it will usually be accepted and that if an alternative hypothesis,  $H_1$ , is true  $H_0$  will usually be rejected. In the most elementary case  $H_0$  and  $H_1$  are *simple* hypotheses; that is, each specifies completely the probability distribution of the generic random variable,  $X$ . Suppose  $f_0(x)$  and  $f_1(x)$  are the probabilities (or probability densities) that  $X$  takes the value  $x$  when  $H_0$  and  $H_1$  are true, respectively.

**Sequential probability ratio test (SPRT).** Wald proposed the following method of sequential hypothesis testing. Independent observations,  $X_i$ , are taken sequentially and result in values,  $x_i$ . Define

two positive constants,  $A_0$  and  $A_1$ . At the  $n$ th stage, calculate

$$\frac{f_{1n}}{f_{0n}} = \frac{f_1(x_1) \cdots f_1(x_n)}{f_0(x_1) \cdots f_0(x_n)}.$$

If  $f_{1n}/f_{0n} \leq A_0$ , accept  $H_0$ ; if  $f_{1n}/f_{0n} \geq A_1$ , reject  $H_0$ . If  $A_0 < f_{1n}/f_{0n} < A_1$ , take the next observation and repeat the procedure.

Wald called this procedure the "sequential probability ratio test" (SPRT). The ratio  $f_{1n}/f_{0n}$ , normally called the "likelihood ratio," plays an important part in the Neyman-Pearson theory of hypothesis testing, a fact that probably largely explains Wald's motivation. The likelihood ratio also occurs naturally in Bayesian inference [see BAYESIAN INFERENCE].

Let  $\alpha$  be the probability of rejecting  $H_0$  when it is true, and let  $\beta$  be the probability of accepting  $H_0$  when  $H_1$  is true. It can be shown that  $A_0 \geq \beta/(1-\alpha)$  and  $A_1 \leq (1-\beta)/\alpha$  and that the SPRT with  $A_0 = \beta/(1-\alpha)$  and  $A_1 = (1-\beta)/\alpha$  will usually have error probabilities  $\alpha'$  and  $\beta'$  rather close to  $\alpha$  and  $\beta$ . (The inequalities arise because sampling usually stops when the bounds  $A_0$  and  $A_1$  are slightly exceeded rather than equaled.)

The number of observations,  $n$ , required before a decision is reached is a random variable. Wald gave approximate formulas for  $E_0(n)$  and  $E_1(n)$ , the mean number of observations when  $H_0$  or  $H_1$  is true. Wald conjectured, and Wald and Wolfowitz (1948) proved, that no other test (sequential or not) having error probabilities equal to  $\alpha'$  and  $\beta'$  can have lower values for either  $E_0(n)$  or  $E_1(n)$  than those of the SPRT.

As an example, suppose that  $H_0$  specifies that the proportion,  $p$ , of "marked" individuals in a large population is  $p_0$  and that  $H_1$  states that  $p$  is  $p_1$ , where  $p_1 > p_0$ . At the  $n$ th stage, if  $x$  marked individuals have been found, the likelihood ratio is

$$\frac{f_{1n}}{f_{0n}} = \frac{p_1^x (1-p_1)^{n-x}}{p_0^x (1-p_0)^{n-x}}.$$

Sampling will continue as long as

$$\frac{\beta}{1-\alpha} < \frac{p_1^x (1-p_1)^{n-x}}{p_0^x (1-p_0)^{n-x}} < \frac{1-\beta}{\alpha},$$

using the appropriate formulas for the bounds. Taking logarithms, this inequality is

$$\begin{aligned} \log\left(\frac{\beta}{1-\alpha}\right) &< x \log\left(\frac{p_1}{p_0}\right) + (n-x) \log\left(\frac{1-p_1}{1-p_0}\right) \\ &< \log\left(\frac{1-\beta}{\alpha}\right) \end{aligned}$$

or  $a_0 + bn < x < a_1 + bn$ ,

where  $a_0$ ,  $a_1$ , and  $b$  are functions of  $p_0$ ,  $p_1$ ,  $\alpha$ , and  $\beta$ . The SPRT can thus be performed as a simple graphical procedure, with coordinate axes for  $x$  and  $n$  and two parallel boundary lines,  $x = a_0 + bn$  and  $x = a_1 + bn$  (see Figure 1). The successive

Figure 1 — Sequential probability ratio test for binomial sampling

values of  $X$  are plotted to form a "sample path," and sampling stops when the sample path crosses either of the boundaries.

Graphic solutions with parallel lines are also obtained for the test of the mean of a normal distribution with known variance and for the parameter of a Poisson distribution.

The SPRT is clearly a powerful and satisfying procedure in situations where one of two simple

hypotheses is true and where the mean number of observations is an appropriate measure of the sampling effort. Unfortunately, some or all of these conditions may not hold. A continuous range of hypotheses must usually be considered; the hypotheses may not be simple; and the variability of the number of observations, as well as its mean, may be important.

Suppose that there is a single parameter,  $\theta$ , describing the distribution of interest, and further suppose that  $H_0$  and  $H_1$  specify two particular values of  $\theta$ :  $\theta_0$  and  $\theta_1$ . For every value of  $\theta$ , including  $\theta_0$  and  $\theta_1$ , quantities of interest are the probability,  $L(\theta)$ , of accepting  $H_0$  (called the "operating characteristic" or O.C.) and the average number of observations,  $E_s(n)$  (called the "average sample number," ASN, rather than the "average sample size," for obvious reasons). Approximate formulas for both these quantities are found in Wald's book (1947). The O.C. is an approximately smooth function between 0 and 1, taking the values  $L(\theta_0) = 1 - \alpha$ ,  $L(\theta_1) = \beta$  (see Figure 2). The ASN, that is,  $E_s(n)$ , normally has a maximum for a value of  $\theta$  between  $\theta_0$  and  $\theta_1$  (see Figure 3). In the binomial problem discussed above, for example, the maximum ASN occurs close to the value  $p = b$ , for which, on the average, the sample path tends to move parallel to the boundaries. It is remarkable, though, that in many situations of practical interest this maximum value of the ASN is less than the size of the nonsequential procedure that tests  $H_0$ .

Figure 2 — Typical form of operating characteristic (O.C.)

Figure 3 — Typical form of average sample number curve

and  $H_1$  with the same error probabilities as the SPRT.

*Closed procedures.* It can be shown in most cases that an SPRT, although defined for indefinitely large  $n$ , must stop some time. Individual sample numbers may, however, be very large and the great variability in sample number from one sample to another may be a serious drawback. Wald suggested that the schemes should be "truncated" by taking the most appropriate decision if a boundary had not been reached after some arbitrary large number of readings. The properties of the SPRT are, however, affected unless the truncation sample size is very high, and a number of authors (Bross 1952; Armitage 1957; Anderson 1960; Schneiderman & Armitage 1962) have recently examined closed procedures (that is, procedures with an upper bound to the number of observations) of a radically different type. In general, it seems possible to find closed procedures which are only slightly less efficient than the corresponding SPRT at  $H_0$  and  $H_1$  but which are more efficient in intermediate situations. (For an account of the use of closed procedures in trials of medical treatments, see Armitage 1960.) Frequently the hypotheses to be tested will be composite rather than simple, in that the probability distribution of the observations is not completely specified. For example, in testing the mean of a normal distribution the variance may remain unspecified. Wald's approach to this problem was not altogether satisfactory and recent work (for example, following Cox 1952) has tended to develop analogues of the SPRT using sufficient statistics where possible [see SUFFICIENCY]. A sequential  $t$ -test of this type was tabulated by Arnold (see U.S. National Bureau of Standards 1951). The usual approximations to the O.C. and ASN do not apply directly in these situations. Cox (1963) has described a large-sample approach based on maximum likelihood estimates of the parameters.

*Two-sided tests of hypotheses.* In many statistical problems two-sided tests of hypotheses are more appropriate than one-sided tests. In an experiment to compare two treatments, for example, it is customary to specify a null hypothesis that no effective difference exists and to be prepared to reject the hypothesis if differences in either direction are demonstrable. One approach to two-sided sequential tests (used, for example, in the standard sequential  $t$ -test) is to allow an alternative composite hypothesis to embrace simple hypotheses on both sides of the null hypothesis. It may be more appropriate to recognize here a three-decision problem, the decisions being to accept the null hypothesis

(that is, to assert no demonstrable difference), to reject it in favor of an alternative in one direction, or to reject it in the other direction. A useful device then is to run simultaneously two separate two-decision procedures, one to test  $H_0$  against  $H_1$  and the other to test  $H_0$  against  $H'_1$  where  $H_1$  and  $H'_1$  are alternatives on different sides of  $H_0$  (see Sobel & Wald 1949).

*Other approaches.* Wald's theory and the sort of developments described above are in the tradition of the Neyman-Pearson theory of hypothesis testing, with its emphasis on risks of accepting or rejecting certain hypotheses when these or other hypotheses are true. This approach is arbitrary in many respects; for example, in the SPRT there is no clear way of choosing values of  $\alpha$  and  $\beta$  or of specifying an alternative to a null hypothesis. Much theoretical work is now based on statistical decision theory [see DECISION THEORY; see also Wald 1950]. The aim here is to regard the end product of a statistical analysis as a decision of some sort, to measure the gains or losses that accrue, under various circumstances, when certain decisions are taken, to measure in the same units the cost of making observations, and to choose a rule of procedure that in some sense leads to the highest expectation of gain. Prior probabilities may or may not be attached to various hypotheses. With certain assumptions, the SPRT emerges as an optimal solution for the comparison of two simple hypotheses, but there is no reason to accept it as a general method of sequential analysis. Chernoff (1959) has developed a large-sample theory of the sequential design of experiments for testing composite hypotheses. The aim is to minimize cost in the limiting situation in which costs of wrong decisions far outweigh costs of experimentation. Account is taken of the choice between different types of observation (for example, the use of either of two treatments). A somewhat different approach (for instance, Wetherill 1961) is to stop an investigation as soon as the expected gain achieved by taking a further observation is outweighed by the cost of the observation. The formulation of the problem requires the specification of prior probabilities and its solution involves dynamic programming [see PROGRAMMING].

The recent interest shown in statistical inference by likelihood, with or without prior probabilities, has revealed a conflict between this approach and the more traditional methodology of statistics, involving significance tests and confidence intervals [see LIKELIHOOD]. In the likelihood approach, inferences do not depend on stopping rules. There is, on this view, no need to have a separate theory of estima-

tion for inverse sequential sampling or to require that investigations should follow a clearly defined stopping rule before their results can be rigorously interpreted.

The effect of all this work is at present hard to assess. The attraction of a global view is undeniable. On the other hand, the specification of prior distributions and losses may be prohibitively difficult in most scientific investigations.

A number of workers have studied problems involving progressive changes in experimental conditions. Robbins and Monro (1951) give a method for successive approximation to the value of an independent variable, in a regression equation, corresponding to a specified mean value of the dependent variable. Similar methods for use in stimulus-response experiments are reviewed by Wetherill (1963). In industrial statistics much attention has been given to the problem of estimating, by a sequence of experiments, the set of operating conditions giving optimal response. This work has been stimulated mainly by G. E. P. Box, whose *evolutionary operation* is a method by which continuous adjustments to operating conditions can be made [see EXPERIMENTAL DESIGN, article on RESPONSE SURFACES].

## SERRA, ANTONIO

Antonio Serra was an Italian economist born around the middle of the sixteenth century in Cosenza, a city of Calabria then belonging to the Kingdom of Naples. Nothing is known about his life except that he spent some time in a Neapolitan prison, charged—according to different sources—either with forging money or with participating in a conspiracy, headed by his fellow citizen Tommaso Campanella, to overthrow the Spanish government; it was in prison that he wrote his *Breve trattato delle cause che possono far abbondare li regni d'oro e d'argento, dove non sono miniere, con applicazione al regno di Napoli* (1613; "A Brief Treatise on the Causes That Can Make Gold and Silver Plentiful in Kingdoms Where There Are No Mines, With Application to the Kingdom of Naples"). Serra may have written *Breve trattato* and dedicated it to the Spanish viceroy in the hope of regaining his freedom. In 1617, while still in prison, he obtained permission to submit to the court his ideas for economic reform; but his plan was not accepted and he was sent back to prison. Serra's work remained practically unknown until Ferdinando Galiani extolled it in one of the footnotes to the 1780 edition of his *Della moneta* ([1750] 1915, pp. 344–345).

Serra refuted the view expressed by Marc'Antonio de Santis, author of *Discorso intorno alli effetti che fa il cambio in regno* (1605; "Discourse on the Effects of the Rate of Exchange in the Kingdom"), that the scarcity of money in the Kingdom of Naples was attributable to the high rate of exchange. He used arguments which made him the first to elaborate the view that the rate of exchange is a consequence of the balance of international payments, which alone regulates the international flow of money (Tagliacozzo 1937, p. xxx; Schumpeter 1954, p. 354).

Serra had a clear understanding of the balance-of-trade concept as an analytic tool in economic reasoning and was the first to use that tool fully and, on the whole, correctly. [See INTERNATIONAL MONETARY ECONOMICS, article on BALANCE OF PAYMENTS.] In analyzing the component items of the balance of payments, he paid due attention to the invisible items; in this respect he anticipated and surpassed all other seventeenth-century writers, including the overrated Thomas Mun, whose *England's Treasure by Foreign Trade* was written about fifty years after the *Breve trattato* and may have been influenced by it (Mazzei 1924, p. 396; Schumpeter 1954, pp. 353–354; Tagliacozzo 1937, pp. xxx–xxxiii).

Serra's book went beyond the immediate implications of its title, explaining the outflow of gold and silver from the Kingdom of Naples and the balance of trade as consequences of the economic conditions of the country.

Essentially, the treatise is about the factors on which depend the abundance not of money but of *commodities*—natural resources, quality of the people, the development of industry and trade, the efficiency of government—the implication being that if the economic process as a whole functions properly, the monetary element will take care of itself and not require any specific therapy. And this argument contains several contributions to the nascent stock of theoretical tools. (Schumpeter 1954, p. 195)

Hence, Schumpeter credits Serra "with having been the first to compose a scientific treatise, though an unsystematic one, on Economic Principles and Policy" (*ibid.*).

One of the theoretical tools contained in the *Breve trattato* (part 1, chapter 3) is the first clear formulation of the law of diminishing returns in agriculture and increasing returns in manufacturing industries [see Tagliacozzo 1937, p. xxxd; see also PRODUCTION].

Serra's realistic, active approach to economic policy—exemplified by his plea for the introduction of new industries in the Kingdom of Naples (see *Breve trattato*, part 3, chapter 8)—probably struck Galiani ([1750] 1915, pp. 344–345) as an anticipation of his own relativistic, undogmatic, pragmatic, liberal (as opposed to laissez-faire) approach. [See the biography of GALIANI; on Galiani's approach to economic policy, see Tagliacozzo 1937, pp. lii–lv.] This is what caused Friedrich List—the founder of the "infant-industry" argument and a forerunner of the historical school of economics—to say, in a chapter devoted almost entirely to Serra (1841, book 3, chapter 1 in 1856 edition), "Antonio Serra sees the nature of things as it actually exists and not through the spectacles of previous systems or of some one principle which he is determined to advocate and carry out."

### I

#### ANIMAL SEXUAL BEHAVIOR

Animal sexual behavior is but one aspect of the total pattern of reproductive behavior. Sexual be-

havior includes all responses directly associated with genital stimulation and copulation, whether homosexual or heterosexual. Among warm-blooded vertebrates, heterosexual copulation culminates in the transfer of sperm from male to female, with subsequent fertilization of ova and reproduction of the species.

Despite its significance for species survival, sexual behavior has received relatively little experimental attention. With few exceptions, sexual behavior in man has not been studied experimentally and is likely to remain generally inaccessible for study by experimentalists for some time to come (Ford & Beach 1951; Lloyd 1964). Careful experimental analysis of animal sexual behavior, especially that of primates, should provide a valuable background of information for understanding the data that exist concerning sexual behavior in man. Many of the forms of sexual behavior described by Kinsey and his associates (Kinsey et al. 1948, 1953) as part of the human sexual behavior repertoire have been observed in a number of other mammalian species. Beach (1949) has suggested that a study not only of the similarities but of the differences in sexual behavior between man and other mammalian species should help in our understanding of how social forces can modify a basic biological drive.

In experimental research on sexual behavior, as in research on any other aspect of behavior, the experimentalist seeks to discover and analyze those variables of which behavior is a function. The initial step in the process is the identification of components of sexual behavior and a description of these in relation to the total pattern. It then becomes possible to measure quantitatively the latency, frequency, and duration of each component and thus to assess the effects of the independent variables on specific components of the total sexual behavior pattern.

Since there have been many reviews of sexual behavior patterns of a number of insects, fishes, amphibians, reptiles, and birds, the present account is restricted to a discussion of sexual behavior in placental mammals. Detailed descriptions are available of the mating behavior of several laboratory mammals, including the rat, guinea pig, hamster, rabbit, cat, dog, monkey, and chimpanzee, and of farm animals such as the goat, sheep, cow, pig, and horse. Limited descriptions are also available of sexual behavior patterns in normally wild species not generally found in laboratories, such as the chinchilla, porcupine, skunk, mink, fox, and elephant. The accuracy and detail of the descrip-

tions of the behavior in the last-mentioned species vary widely, however, and further study is needed.

### Components of sexual behavior

**Mounting.** The most readily identified aspect of animal sexual behavior is the mounting response. It is an essential component of the male mating pattern but frequently occurs in females, especially during estrus. In a successful mating sequence the male mounts the female from the rear. The forelegs are placed on the back or around the sides of the female with the hind legs on the ground. The male may then execute a series of rapid pelvic thrusts. The posture and motion permit the male to insert the erect penis into the female's vagina. Not all mounting, however, is oriented to the rear of the female. The male may mount the side or head of the partner and may or may not execute pelvic thrusts. Mounting by females also shows similar variation. Females of a number of species display mounting behavior only during estrus; but in some species, such as the rat and dog, mounting by females is not restricted to any particular part of the estrous cycle. The mount executed by a female is frequently indistinguishable from that of the male. Thus, the typography of the behavior does not identify the sex of the animal. Mounting occurs between members of the same or opposite sex and across species in some instances.

**Intromission.** Intromission is obviously restricted to the male. To achieve intromission, not only must the male be properly oriented, but the penis must be erect. The detection of intromission is difficult in most species and often requires special conditions of observation. In some species, such as the guinea pig, the rate of pelvic thrusting may be slower during intromission. In the rat, when intromission is not accompanied by ejaculation, the intromission response is usually followed by a vigorous backward lunge and a period during which the male may manipulate the penis with paws and mouth before mounting again. This gross bodily reaction is most frequently used as an index of intromission rather than visualization of penis insertion.

**Ejaculation.** Ejaculation, as in the case of intromission, is not identified directly but is commonly inferred by changes in gross body movement. In the guinea pig, for example, at the moment of ejaculation the flanks of the male are drawn in as in a spasm. The male then dismounts, or the female pulls away, and both male and female clean the genitalia. Ejaculation by the male rat is also accompanied by a drawing in of the flanks. Follow-

ing ejaculation the male dismounts much more slowly than he does following intromission, and there ensues a period of relative inactivity. Judging whether or not ejaculation has occurred from observation of gross behavior is particularly difficult in some species, and the presence of sperm or an ejaculatory plug in the vagina is frequently used as confirmatory evidence.

**Lower components.** Not only is mounting the most conspicuous aspect of sexual behavior but together with intromission and ejaculation shows for most species the least variation among the numerous components of the sexual behavior pattern. Wide variation exists from species to species in the so-called lower components of the mating pattern. In general, these lower components appear to produce excitement and readiness to mate in both sexes. The guinea pig displays a mating pattern typical of many species. The following sequence is characteristic: On encountering an estrous female, the male, walking with a characteristic gait, circles the female; he rubs against her flanks, nibbles at the ear, prods the female's mouth area with his nose, licks the genitalia, then approaching from the rear, rubs his nose and lower jaw over the female's back, a response that frequently elicits the lordosis response in the receptive female.

These lower components may occur in any order and do not represent a stereotyped sequence of reflexes triggered by the presence of an estrous female. In some instances, especially in experienced individuals, the male may mount the female without any preliminary display and may achieve intromission and ejaculation without manifesting any of the lower components.

**Lordosis.** The one outstanding component of female sexual behavior common to all mammalian species except man is the lordosis response. In the monkey the receptive posture is referred to as a "present." The receptive posture or lordosis consists of a particular stance, with the four legs fixed and a straightening and arching (in some cases) of the back with elevation of the pudendum. In some species the head is thrown backward and the tail is deviated or displaced so as to expose the genitalia. A number of minor species differences exist, but in all species the pattern facilitates both mounting and intromission by the male.

The complete pattern of female sexual behavior may include a number of other components in addition to the lordosis response. These additional components vary widely among species. They may precede copulation and may be classed as courtship

behavior or "foreplay" or precede the onset of full estrous behavior as in the guinea pig and be referred to as proestrous behavior. In some species, such as the cat, estrus may be followed by distinct behavioral responses, termed afterreaction.

### Factors influencing sexual behavior

Accurate description of sexual behavior in natural surroundings and under carefully controlled laboratory conditions, although an essential first step, constitutes but a starting point for the study of the major problems associated with sexual behavior. In experimental investigation, sexual behavior has been found to vary with the species, strain, sex, diet, temperature, illumination, season, age, method of rearing (including age of weaning), nature of housing (including social and isolated conditions), stage in the reproductive cycle, familiarity with the test area (territoriality) and test partner, duration and frequency of tests, dominance relationship, and the general health of the animal. With the exception of masturbation, sexual behavior is a social phenomenon; hence the behavior of each individual of a pair or group constitutes an added stimulus variable not readily controlled in the assessment of sexual behavior. It is frequently convenient to classify the determinants of sexual behavior into a few broad categories. Such categories are usually neither all-inclusive nor mutually exclusive but suggest, in a general way, the class of variable emphasized by an investigator or represented in a given research effort. For purposes of presentation we may categorize the variables as genetic, hormonal, sensory and neural, and experiential.

**Genetic variables.** Chromosomal sex is determined at the time of fertilization and depends upon the particular chromosomes contributed by the parents. Many problems of sex determination at the gene level of analysis remain to be solved, but these need not concern us here. Classification of the individual as male or female is usually based on the appearance of the external genitalia. Unfortunately sex classification based on this criterion does not always correspond to chromosomal or gonadal sex, nor does it necessarily correspond to the pattern of sexual behavior displayed by the animal. In addition to these possible inconsistencies, chromosomal sex itself may not be normal, as for example in the case of an individual whose chromosomal pattern is XO and who, accordingly, lacks one of the sex chromosomes. Nevertheless, species differences, strain differences, and sex differences may be changed by varying genetic background. Such knowledge contributes little to our under-

standing of how the genes bring about their effect; but regardless of the mechanisms involved, it is assumed that all organismic variables have a genetic basis (Beach 1947a).

**Breeding experiments.** The genetic material contributed by the parents has been shown to determine the particular pattern of sexual behavior that will be displayed by the individual as an adult. Not only is it possible to breed for high or low levels of sexual behavior, but different modes of inheritance of the various components of sexual behavior have been demonstrated. For example, in a study of two inbred strains of guinea pigs, in which the male of the two strains differed in ejaculation latency and in mounting frequency, Jakway (1959) has shown that ejaculation latency of one strain was dominant and mounting frequency of the second strain was dominant when these were studied in  $F_1$  and  $F_2$  hybrid generations and in backcrosses. Differences have also been demonstrated in modes of inheritance of components of female sexual behavior in the guinea pig (Goy & Jakway 1959). It is obvious that sexual behavior need not be inherited as a unitary trait. Although most work on the inheritance of patterns of sexual behavior has been carried out on insects, an increasing amount of work is being done on mammals (Dilger 1962; Goy & Jakway 1962).

**Hormone variables.** Sexual behavior among females of lower mammalian species is characterized by its cyclicity. The display of sexual behavior is referred to as estrus or heat. The period coincides with the presence of mature ovarian follicles and, generally, with changes in the vaginal epithelium. The term estrus is sometimes used to refer to the physiological state of the ovary or condition of the cells in the vagina. The multiple meaning attached to the term is testimony to the close relationship between the physiological state and the behavioral state. Ovulation usually, although not always, accompanies estrus, and thus mating is most likely to occur at a time when fertilization is possible. Among primates, such as the monkey, chimpanzee, and man, the display of sexual behavior is not confined to the period of ovulation but may occur at any point in the cycle (Eayrs & Glass 1962; Young 1941). The decreasing dependency on ovarian hormones has been taken as evidence that animals higher on the phylogenetic scale have through evolution become emancipated from gonadal hormone control of sexual behavior (Beach 1947b).

Females and males of some species, such as the marten and deer, are seasonal breeders. Sexual activity among seasonal breeding males is likely to be confined to periods when the females of the

species are in estrus. Among nonseasonal breeding species, males do not show the cyclic display of sexual behavior characteristic of the females. Correspondingly the level of gonadal hormone in the male does not vary in any cyclic fashion.

*Gonadectomy and replacement therapy.* Perhaps the most compelling evidence of the importance of the gonadal hormones in the display of sexual behavior comes from studies of gonadectomy and replacement therapy.

Spaying adult females of subprimate species, with the possible exception of the rabbit, results in the complete and immediate loss of mating behavior. But the injection of estrogen or estrogen and progesterone brings the female into estrus. With appropriate timing and dosage of injected hormone, estrus thus induced may be indistinguishable from that displayed prior to spaying. In primates below man, the effects of spaying are not as conspicuous as in lower mammals, and although the effectiveness of replacement therapy has not been as carefully studied, reports suggest that the dramatic change in behavior observed in lower mammals is not seen in primates. The effects of ovariectomy on human sexual behavior are not fully known, but some sexual behavior is known to persist following the operation. In general, the less conspicuous are the changes in behavior at estrus, the less effective ovariectomy appears to be in eliminating receptivity.

Castration of the adult male does not result in complete and immediate loss of sexual behavior as does spaying in the female. The first component of the mating pattern to be lost following castration is the ejaculatory response, and later intromission drops out of the repertoire. There is considerable species variation, but in many species the male may continue to mount and show pelvic thrusts months or years after castration. The decrement in performance is generally greater in rodents and lagomorphs than in carnivores (Beach 1958). Information on the effects of castration in primates is scanty. Present evidence suggests that the prepuberally castrated monkey and ape retain the capacity for erection, and they display the normal mounting pattern (Goy 1964). Little is known of effects of castration on human sexual behavior.

Just as there is a gradual diminution of sexual behavior following castration, restoration of the complete pattern of sexual behavior by androgen administration is a gradual process. An increased frequency of mounting is followed by the occurrence of intromission and finally the ejaculatory response is restored. Such, at least, is the case in the lower mammals that have been studied. No

quantitative studies exist on the effectiveness of androgen replacement therapy in subhuman primates, and the evidence for man is contradictory.

There is no question of the importance of sex hormones for the full expression of sexual behavior in adults of lower mammalian species; however, sex hormone specificity remains somewhat ambiguous. In either sex the heterotypic hormone is not as effective as the homotypic hormone in promoting the display of appropriate sexual behavior. In general, the character of the behavior induced by hormone injection, whether masculine or feminine, is not a property of the hormone itself but depends upon the organization of the sexual behavior mechanisms within the individual.

The role of gonadal hormones in differentiation of biological sex has been studied intensively by embryologists over many years (Burns 1961), but the role of these hormones in differentiation of sexual behavior has, until recently, received little attention.

It has now been demonstrated that in both the genetic female guinea pig and the rat, testosterone administration during the period of differentiation of the tissues that are to mediate sexual behavior, or what we have called sexual behavior mechanisms, results in permanent suppression of female behavior and in an increase in display of male behavior. In the guinea pig, this period of differentiation is completed prenatally, whereas in the rat the period extends into the early postnatal period. The behavior of genetic female adult rhesus monkeys treated prenatally with testosterone has not been studied, but observation of behavior during the first year of life showed a masculinization of patterns of play behavior and indications of an increase in the frequency of display of male sexual behavior (Phoenix et al. 1959; Young et al. 1964).

Further evidence indicating the significance of testosterone in differentiation of tissues mediating the pattern of sexual behavior is provided by the response of rats castrated the day of birth and injected as adults with estrogen and progesterone. These males displayed the complete female estrous response with a lordosis frequency comparable to that of females. Such was not the case when rats were castrated at ten days of age or later.

In adulthood the role of testosterone is to activate pre-established patterns of sexual behavior. During the prenatal or early postnatal period the role of testosterone is organizational, in the sense that it differentiates in both genetic males and females a prepotency for the male pattern of sexual behavior (Young et al. 1964).

The gonadal hormones are major determinants

of sexual behavior both as activators and organizers of patterns of sexual behavior. The non-gonadal hormones play a less direct role in control of sexual behavior. The pituitary, for example, derives its significance for behavior primarily because it controls gonadal action. Sexual behavior can be induced in hypophysectomized animals by injection of gonadal hormones, but in otherwise intact animals pituitary dysfunction is associated with abnormal reproductive function and sexual behavior.

**Thyroid activity.** Broad species and individual differences exist with respect to the importance of thyroid activity. The thyroid is not crucial to normal sexual behavior in the male guinea pig or rat. The thyroidectomized female rat may mate successfully but the spayed, thyroidectomized guinea pig exhibits reduced responsiveness to injected estradiol. In the bull, thyroidectomy abolishes all sexual behavior. Present evidence emphasizes species differences, and when thyroid deficiency appears to interfere with normal sexual behavior it most likely does so by altering systemic metabolic function.

**Sensory variables.** The senses serve several functions vital to sexual behavior. They are essential in bringing together the male and female of a given species and in arousing and directing behavior that eventually results in copulation and reproduction. The distance receptors play a major role in locating appropriate sex partners, and all of the senses probably contribute to the arousal and performance of the behavior sequence culminating in insemination.

The effects of sensory deprivation in sexual behavior have been studied to a limited extent in the rat, rabbit, and cat. Beach (1951) has concluded that sexual arousal in the male does not depend upon any one sense modality but upon the total pattern of sensory input from the several receptor systems. Generally the female is less dependent upon multiple stimulation for display of adequate sexual behavior. A female deprived of vision, olfaction, and audition may continue to mate successfully, but this is not true of the male.

**Neural variables.** The neural tissues constitute what is presumed to be one of the primary loci of gonadal hormone action controlling behavior. The site of action within the nervous system is not definitely known, but it is assumed to include both spinal cord and brain.

**Spinal cord.** When the cord is transected above the lumbar region in males of species ranging from rat to man, stimulation of the penis still produces erection, ejaculation, and pelvic thrusting. The majority of paraplegics can achieve erection, and some

have had fertile matings. It is obvious, therefore, that at least some of the more reflexive elements of the sexual behavior pattern are organized at the spinal level. Effects of cord transection in the female are not as clear, but whatever fragmentary elements of sexual behavior survive cord transection occur independently of hormonal stimulation. In neither sex is there anything resembling the normal pattern of sexual behavior in preparations with the brain stem sectioned below the level of the hypothalamus.

**Hypothalamus.** Small bilateral and midventral lesions in the hypothalamus of spayed female guinea pigs may eliminate all receptive behavior and mounting despite hormonal injection, which in the spayed unoperated female induces the complete estrous response (Brookhart et al. 1940). In some females with slightly different lesions, receptive behavior is blocked but mounting behavior is unaffected. In still other cases, mounting is eliminated but receptive behavior persists (Goy & Phoenix 1963). In the male guinea pig, hypothalamic lesions may eliminate all sexual behavior. However, some males may continue to mount following the operation. In the absence of testicular atrophy, loss of sexual behavior cannot be attributed to hormonal insufficiency (Brookhart & Dey 1941; Phoenix 1961).

Hypothalamic lesions in a number of species, including the rat (Soulairac & Soulairac 1956), rabbit, cat, and ewe, have resulted in comparable loss of sexual behavior. In most of these species, although not yet established for both sexes, one area in or near the hypothalamus controls pituitary function and thus governs sexual behavior indirectly; and a second area exerts direct neural control over sexual behavior. Destruction of the former eliminates sexual behavior by interfering with pituitary gonadal axis function and therefore with output of gonadal hormone necessary to normal sexual behavior. Destruction of the latter area eliminates sexual behavior by interfering with a primarily neural mechanism (Sawyer 1960).

Lesions in the anterior portion of the hypothalamus in spayed female rats and guinea pigs have produced persistent receptivity, or estrus. Such an operation releases the animal, to some extent at least, from gonadal hormone control of sexual behavior and thus produces a condition thought to exist normally in a number of primates, especially man. The operation may be interpreted as removing a neural area that in the normal state inhibits sexual behavior unless stimulated by female hormones (Goy & Phoenix 1963).

A number of other lines of evidence implicate

the hypothalamus as the region of the brain most directly involved in the control and integration of sexual behavior. For example, hypothalamic implants of solid diethylstilbestrol dibutyrate produce in the spayed cat the full display of sexual behavior. Comparable implants in other regions of the brain or in subcutaneous tissue do not produce this effect (Harris et al. 1958).

Experiments involving electrical recording from hypothalamic areas in the cat have shown changes in potential associated with estrous reactions, and changes in electroencephalograph activity of the anterior hypothalamus have also been observed in association with mating behavior in the female rabbit (Sawyer 1960).

When an electrode is permanently implanted in the hypothalamus of a rat and so wired that pressing a bar delivers a small electrical impulse to the brain area at the electrode tip, rats will repeatedly press the bar, thus obtaining electrical stimulation to the area. Castration abolishes the bar-pressing response by the rat, but the response can be reinstated by injecting the castrate with testosterone (Olds 1958). Such a demonstration tells us little about sexual behavior but implicates the hypothalamus in behavior that is dependent on a gonadal hormone.

In a now classic experiment, Klüver and Bucy (1939) performed bilateral temporal lobectomies on monkeys and reported a broad constellation of behavioral changes, including heightened sexual activity, following the operation. Hypersexuality was later reported following destruction of the amygdaloid complex and overlying pyriform cortex in lynxes, agoutis, cats, and monkeys. Castration of male cats resulted in elimination of hypersexuality. The lesion is interpreted as having had its effect by removing from inhibition the neuroendocrine mechanisms regulating the display of sexual behavior (Schreiner & Kling 1956).

**Cerebral cortex.** In lower mammals, including the cat, complete removal of the neocortex of the female does not eliminate sexual receptivity, although the quality of the response may suffer. In male rats comparable decortication eliminates all sexual behavior, and these males show no signs of arousal in the presence of an estrous female. Partial decortication in the cat may eliminate successful mating behavior because of loss of sensory-motor integration, but the operation need not interfere with sexual arousal (Beach 1951).

In primates the cortex may play a major role in integration of sexual behavior. In general, the more important learning and memory are in sexual performance, the more important the neocortex is likely

to be. It is apparent that control of sexual behavior is not vested in any single brain area. The evidence suggests rather that the entire nervous system is involved in the display of the normal pattern of sexual behavior.

**Experiential variables.** Although it has been pointed out that differences in patterns of sexual behavior are associated with differences in genetic background, this does not preclude the importance of experiential factors in determining the particular pattern displayed by the individual. The limits to which experience can modify the behavior pattern are, however, largely determined by genetic factors. In studying the influence of experiential factors on mating behavior, we are indirectly examining the variability allowed by genetic endowment.

When males from two inbred strains of guinea pigs were separated from their mothers at the age of 25 days and reared in isolation, they did not display normal mating behavior patterns when tested as adults. For isolation to produce comparable effects in male guinea pigs of a heterogeneous stock, the animals had to be isolated beginning at 10 days of age. The experiment demonstrates the influence of genetic and experiential variables in determining patterns of sexual behavior. It should be noted that not all males even within the inbred strains showed the "isolation effect" and that the relevant variables associated with isolation have not been determined (Valenstein et al. 1955).

Isolation of the male rhesus monkey at birth produces drastic effects not only on its sexual behavior but on its entire social behavior repertoire (Harlow & Harlow 1962). However, mother-deprived infants, if given an opportunity to interact with peers, develop essentially normal patterns of sexual behavior. The manner in which peer interaction fosters development of normal sexual behavior remains to be demonstrated.

Female guinea pigs and rhesus monkeys reared in isolation also show deficiencies in reproductive behavior. Despite the bizarre social behavior and abnormal sexual behavior displayed by the isolated female rhesus, a number have mated with particularly capable males and have delivered viable young. It should be noted that the behavioral deficiency is not attributable to gonadal hormone deficiency in the isolated monkey or guinea pig.

Although the exact nature and extent of the effects of isolation on sexual behavior have not been determined for the male rat, available evidence suggests that the impairment is not as profound as it is in the monkey (Zimbardo 1958).

A wide variety of experiences are capable of modifying sexual behavior in addition to the method

of rearing just discussed. What has been demonstrated is that sexual behavior, in general, is subject to modification just as other aspects of behavior can be modified by varying experience. Thus despite heritability of sexual behavior patterns, dependence on hormonal stimulation, and the spinal reflex contribution to patterns of sexual behavior, the complete pattern can be blocked, enhanced, or modified by social and situational experience. The extent to which it can be modified by experience varies primarily with the species, sex, and age of the individual.

## II SOCIAL ASPECTS

Social scientific writing on sexual behavior over the past century falls in three categories: the ecology and styles of sex as a physical act; the meanings of the act, in its direct, displaced, or sublimated form, to the individual and to society; the norms and ethical standards that govern the modes of, occasions for, and designation of participants in, the physical act; and the organizational arrangements that implement these norms and standards. It is now commonly accepted that the frequencies and techniques of sexual behavior vary widely among individuals and among religious, class, ethnic, educational, age, and sex categories in the same society (Kinsey et al. 1948; 1953); that its personal meanings are numerous and contradictory (Freud 1893-1895); and that sexual norms and ethical standards contrast sharply from culture to culture (Mantegazza 1886).

As producers of literature on sexual behavior, social scientists are easily outnumbered by physicians, psychologists, physiologists, theologians, and philosophers, among others. The present article, rather than restricting itself to studies by social scientists, will conceptualize the content of this diverse literature from a social science perspective. These materials will be examined in terms of the social meanings of sexual behavior, the way the sexual enters as a component of social roles, the social norms governing recruitment to these eroticized roles, and their articulation with networks of the noneroticized roles that constitute some major social institutions. Reference will be made to social organizational arrangements for facilitating or inhibiting enactment of these roles.

**The social science perspective.** Sexual behavior participates in social action by contributing a motive, or a driving force of that action. Ratzenhofer (1898), an early theorist of the sociology of sex, saw all motives of social contact as modifications of either the instinct of self-preservation or the sexual instinct. Moreover, as a component of social action, sexual behavior is also a way of expressing and conveying both individual and social meanings; that is, the meaning is not only that which an individual attributes to his act but

also that which society has come to apply to the act (Thomas 1907).

In contrast to the social science perspective, the "physicalist tradition" tends to treat sex simply as energy or motive. For example, the studies of Kinsey (a zoologist) and his associates at the Indiana University Institute for Sex Research follow the tradition of "biological realism"; that is, they focus on the ecology and styles of the physical act. These are by far the most popular scientific studies of sex, as measured by sales and published critical reviews. From a physicalist point of view, the presumption that all acts engaging the genitals are alternative ways of tapping the same reservoir of physiological energy justifies drawing them under the same rubric. Thus Kinsey's treatment of alternative "outlets" places greater emphasis on the channels through which energy is released than on the social context of that energy release.

Social science analyses of sexual behavior are primarily concerned with coital acts, both homosexual and heterosexual, which involve a relationship between human beings and are thus qualitatively different from other sexual behavior. Masturbation, nocturnal emissions, and bestiality claim social science attention only insofar as they affect either the occurrence of coitus or its meaning or become the object of institutional concern. According to this view, the energy problem is interwoven with that of the social meaning of sexual acts. Freudian theory of the economy of the libido uses the notion of sublimation to designate the rechanneling of sexual energy into cultural activities by shifting the object of cathexis; thus the theory interweaves motivational and meaningful aspects.

Sexual behavior contains a nonverbal language through which an individual expresses and conveys meanings; sensory exploration and gestures outweigh words as sign and symbol vehicles. Removal of clothing beyond the degree necessary for coitus itself exemplifies the significance of tactile communication. Any sexual act may carry several social and personal meanings. For example, a morning erection may express unconscious concerns about death rather than sex (Bergler 1950).

Ford and Beach (1951) studied sexual behavior between species and across cultures, yet they granted priority to the physicalist approach by classifying sexual behavior according to modes of stimulation of the genitals. A consequence of this physical perspective is their tendency to measure the cause of sexual behavior in terms of tension reduction and to designate procreation as its prin-

cipal social function. The procreative function loses its centrality for a social psychology of human sexual behavior in view of the empirical fact that less than one in a thousand human coital acts results in pregnancy and fewer are intended to do so (Foote 1954). However, for sociology, the part of sexual behavior that is, in fact, procreative becomes significant because of both the demographic consequences and the institutional and organizational arrangements that become necessary for the birth and rearing of offspring (Ellwood 1925).

**The eroticized role.** The higher a species is in the evolutionary scale, the less dependent is its sexual behavior on gonadal hormones and seasonal physiological changes; and in man it comes under control of the cortex of the brain (Ford & Beach 1951), thus introducing the possibility of decisional and normative control. Sexual behavior as a role component, that is, as a component of social action under decisional and normative control, distinguishes human from animal sexuality.

In human sexual behavior, the erotic element may be incidental to other motives, such as the desire for a new experience or the desire to escape drudgery (Thomas & Znaniecki [1918-1920] 1958, vol. 2, pp. 1800-1821). A social role—such as that of lover, of prostitute or client, of husband or wife, of young male delinquent or adult fellator (A. J. Reiss 1961)—in which a sexual element is embedded with other social role elements, such as economic or affective exchange or child raising, may be termed an "eroticized role." The eroticized role is part of the whole system of roles constituting the personality, and, in a sense, it eroticizes the entire personality. This is what has been described as a transformation of sexuality into Eros (Marcuse 1955). Sexuality becomes meaningful to the actor, and may be understood by the observer, in the context of these other aspects of the personality.

An eroticized social role may be articulated with other roles in the social structure; for example, the role of the prostitute in her relation with a client may be meshed with her relatively non-erotic role in her relation with her madam or other employer. This perspective on role articulation follows Malinowski (1929), who advocated an anthropological perspective that does not treat sex as a mere physiological transaction but studies its implication for lovemaking, its function as the nucleus of the family, the spells and magic that grow up around it, its effects upon, and how it is affected by, the legal system and the economic system.

The variety of sexual meanings is, in part, dependent on other aspects of the role—that is, on other norms, affects, or meanings that define that role or other roles with which it is articulated in a personality or in a society. Kirkendall (1961) described how sex, while it may advance a deep interpersonal relation, may be exploitative as part of a casual relationship. With prostitutes, the relationship itself becomes the instrumental servant of its sexual component. Even in advancing a deep relation, however, sex may assume special meanings associated with the broader meaning of that relationship. Thus sex may be a weapon to destroy, a mode of defense, a bargaining point, or a form of self-assertion; negatively, it may be a form of self-denial (Frank 1954).

Components of an eroticized role may be malintegrated. A marriage contracted for social or economic advantages despite sexual incompatibility is a classic instance. Sexual behavior inconsistent with personal ethical standards may engender an internal struggle manifested in guilt feelings. If strains of this type become widespread, social standards may be readjusted (I. L. Reiss 1960).

### Recruitment to the eroticized role

Recruitment of partners to an eroticized role is governed by considerations of personality, social norms, and societal mechanisms of control. Personality variables affect the desire and ability of an individual to seek, as well as his desirability as, a sex-role partner. Physiological or attitudinal disturbances in an individual's response at any stage of the coital act influence recruitment to the eroticized role. In the preparatory stage, an individual must be able to respond to excitation from internal and external psychological stimulation. This requires sensory, intellectual, motor, and glandular contributions to mechanisms of arousal. An individual's attitude toward himself—for example, as reflected in body image—affects his ability to woo another through foreplay and enter intimate relationships (Fisher & Cleveland 1958). An individual must experience impetus to penetrate or desire to be penetrated, want to continue inplay, and, at culmination, experience orgasmic peristalsis of genital structures. Much depends upon ability to tolerate regression in the service of the ego (Fried 1960). Disturbances of sexuality are commonly classified in terms of frigidity, low potency, preference for masturbation or for sexual perversion, hypersexuality, and lack of sexual interest (Eisenstein 1956).

Special personality groups vary in interest in eroticized roles. Most of the erotic impulse of idiots

is directed toward themselves and the remainder to objects of the same sex (Potter 1927). Alcoholics lack sex interest, because, it has been argued, of repressed homosexuality (Levine 1955). The aged tend to lose motivation for coitus (Armstrong 1963).

The evaluation of personal characteristics in recruitment is relative to the persons involved; that is, an individual not desirable to one partner may be desirable to another. For example, males generally prefer shorter females, and females generally prefer taller males. Women who want men near their own height, it has been argued, are expressing a need for ascendancy. Similarly, males who seek taller women are said to be seeking to possess the forbidden parent figure (Beigel 1954).

**Norms of recruitment.** Social norms prescribe and proscribe which social types may recruit one another. Havelock Ellis (1910), for example, wrote that in choosing a mate we tend to seek parity of racial and anthropological characteristics together with disparity of secondary sexual characteristics and complementarity of psychic characteristics. Under control of instinct, animals rarely depart from parity of species and disparity of secondary sexual characteristics. Mongrelization may be induced among domesticated animals but is extremely rare among wild animals despite opportunities. Man can, and sometimes does, engage in relations that the more constitutionally directed animals would refuse. Man may disregard species parity and practice bestiality, disregard secondary sexual disparity and practice homosexuality, and disregard psychic complementarity and establish neurotic sex relations. On the other hand, man may refuse relations because of sexual style, the status of the partner, or the beauty of the partner—a parity irrelevant to the animal. For man, the power of the social over biological determinants extends to the very definition of gender. Money et al. (1957) compared the relative influences of the chromosomal sex, gonadal sex, hormonal sex, internal accessory reproductive structures, and external genital morphology on the gender role actually assumed by hermaphrodites, and they found social sex assignment to be the most reliable prognosticator of gender role.

Rules for recruitment to coital relations in general parallel, but do not completely overlap with, those governing marital recruitment. Laws of exogamy define the inner social limits for recruitment of a marital partner. These are extensions of the incest taboo, which is a nearly universal taboo, with exceptions only in such cases as the Egyptian royal family, where brother-sister mar-

riage was permitted, or among Azande nobles, where father-daughter marriage has been permitted. Laws of endogamy define the outer social limits. These norms have been compared by Westermarck (1889) to the "law of similarity" that keeps animals from pairing across species. In human relations, however, endogamy controls potentially fertile relations within the same species.

A number of individuals are virtually precluded from recruitment to eroticized heterosexual roles. This is the case with institutionalized populations in prisons or mental hospitals. Likewise, occupational conditions may separate individuals from the opposite sex. Hobos, being homeless, have less access to women, and thus they tend to frequent the lowest status prostitutes and to practice homosexuality.

Social control of eroticized role recruitment contributes to the maintenance of the social structure; if society lacked such controls, random mating could disrupt the familial and economic lines of stratification of a society. Moreover, social control of recruitment may enable one social group to dominate another through its power to allocate sexual occasions and facilities. It may also be an internally integrative device, as it is among celibate monastics. According to Ross (1920), such control is necessary to manage a smoldering antagonism that exists between the sexes as groups.

**Sexual communication in recruitment.** Communication employed for recruitment to the eroticized role parallels the communication of arousal in the sex act. Token arousal announces sexual availability. Erotic communication relies heavily on movement, such as the inviting movements of the dance and the arousing tactile movements during coitus. Odors founded in the natural capryl odors and supplemented at the human level by perfumes act upon the deeper levels of consciousness (Bloch 1907). Cosmetic means of communicating sexual interest include painting and tattooing as well as sexual mutilation. Socially stylized ceremonies of fertility or initiation may announce availability and effect arousal. A few rites, such as subincision, announce sexual availability but reduce sexual enjoyment or arousal potential for the subject (Allen 1949; Westermarck 1889).

Verbal communication supplements sensory communication in sexual behavior. Speech is so closely identified with sexuality that in some cultures it is forbidden or restricted between persons who are socially precluded from engaging in sexual relations (Baker 1949). The more intimate a sexual matter, the less the likelihood of communication about it to nonerotic role partners.

In many societies, socially structured mores about erotic communication bar young people from arousal and consummatory opportunities. Sexual norms may be learned inferentially by the young or by new social groups, such as immigrants, by observation of behaviors lacking primary erotic meaning, such as forms of dress and of association between the sexes (Klausner 1964). Classified newspaper advertising and a specialized journalism directed to erotica have long been used for the recruitment of both heterosexual and homosexual partners.

Deviant subgroups develop private signaling systems to cue a potential partner without revealing themselves to noninitiate spectators. For example, homosexuals may wear peculiar clothing (the definition of which changes from time to time), intersperse their speech with a special argot, or perform certain gestures. They may position themselves to receive such signals by frequenting known haunts.

### Social control of sexual behavior

Society not only exerts control over the recruitment of role partners but also attempts to control the types of sexual behaviors enacted and the occasions for their enactment. Both informal and formal social controls are found. Attitudinal disapproval of individuals' erotic behaviors, which is perhaps the commonest form of control, may be expressed as verbal chastisement, gossip, scandal, humor, or mockery. The Trobriand Islanders, for example, control sexual style by jesting about those who use the "white man's position" for intercourse. A quasi-formal control mechanism is exemplified among the Mondurucu by the gang rape to force a recalcitrant female to submit to male authority (Murphy 1959).

Norms also define those behaviors to which it is legitimate to recruit. Early studies of sexual behavior treated cross-cultural comparisons descriptively, presenting various behaviors, sexual art, and technical devices as curiosities (Moll 1912; Kraftt-Ebing 1886; Bloch 1907). These studies did, however, open the way to the study of sexual norms by giving information about criteria for recruitment to eroticized roles in other cultures. Correlations between sexual behavior and the overarching cultural ethos allow inference about the types of sexual behaviors to which recruitment is approved in various cultural situations; that is, recruitment norms vary with the ethos. For example, Sorokin (1956) argued that sexual asceticism is associated with "idealistic societies" and libertarianism with "sensate societies." Taylor (1953) classified histor-

ical periods in Western society as predominantly "matristic" or "patristic." In patristic periods, dominated by a father religion and exemplified by England during the first millennium of the Christian era, people have a horror of homosexuality, sex is generally restricted, and rape and incest increase. In matristic periods, dominated by a mother religion and exemplified by England after the first millennium, people have a horror of incest and are permissive regarding sex.

Social control may be exerted by concrete organizational arrangements. Organizations that facilitate recruitment to the sex role also maintain procedures, such as the "sex game," for controlling recruitment and defining types of permitted alliances (e.g., see Cressey 1932). The Nazis, while promoting a policy of sexual abstinence, provided youth camps in which sexual relations took place. Monasteries may debar their inmates from sexual opportunities. Child marriage commits the relationship before the erotic drive appears. The sexes may be physically and, therefore, socially isolated, as in a harem or school. Chaperonage is a way of supervising the young during their meetings. Systems of peer group pressures, such as those exerted by campus sororities or fraternities, encourage socially approved love relationships by subjecting them to ratings by age mates. These controls are more stringent among the upper classes, who have more to lose by a breakdown in the stratification system (Goode 1959).

Legal control takes the form of laws against homosexuality, adultery, sodomy, or pederasty—that is, against behaviors that violate rules governing recruitment to the eroticized role. In some jurisdictions, the style of coitus is legally as well as informally directed. In England, the Wolfenden Committee on homosexual offenses and prostitution gathered intelligence about sexual behavior from social scientists and psychiatrists as a basis for legislating on sexual recruitment. They concluded that it is the duty of the law not to concern itself with immorality as such but to confine itself to activities that offend against public order and decency. Thus, they recommended that homosexual relationships between adults by mutual consent and in privacy should not fall within the province of criminal law (Great Britain . . . 1957). Federal legislation in the United States, such as the Mann Act (the so-called "white slave" traffic act) of 1910, is given force through policing activities of the Immigration and Naturalization Service, the Federal Bureau of Investigation, and local police departments. Throughout Anglo-American history,

the methods of legal control of sex expression have varied much more than has the accepted doctrine of sexual morality (May 1931; Mueller 1961).

Sex education is a form of noncoercive, though formal, control. The medical profession in its efforts to control venereal disease, as well as religious groups in their efforts to maintain their own sexual norms, have been instrumental in founding organizations such as the American Society of Sanitary and Moral Prophylaxis in 1905 and the American Social Hygiene Association in 1912, now the American Social Health Association. This latter association uses education to combat venereal disease, commercialized prostitution, and other conditions associated with sex delinquency among young people.

**Resistance to social control.** Protest against efforts to enforce prevailing sexual mores and to control recruitment to the eroticized role is expressed in individual sexual deviance, the formation of groups of individuals with special sexual needs, and movements to change the prevailing mores. The sex offender uses illegitimate means, such as violence or disregard for the consent of the partner, to recruit to coital or noncoital sexual behaviors, or he recruits without regard to rules defining permitted sexual partners. Generally, these individuals are undersexed rather than oversexed. Freudian theory suggests that some sex offenders may be compensating for feelings of bodily damage or phallic inadequacy, or suffering from castration anxiety (Hammer 1957). Most sex offenders are of average intelligence. Those arrested for incest, however, tend to be older men of subnormal intelligence and antisocial personalities. Apprehended distributors of obscene literature tend to be older, sexually inhibited men of average intelligence who are not hostile. Women are rarely arrested for sexual offenses in American society, except for violating norms regarding public solicitation. The role relations in primarily nonsexual delinquent groups may become eroticized, involving, for instance, group masturbation.

Organizations of individuals whose physical status makes it difficult for them to recruit or be recruited to an eroticized role, such as dwarfs or the blind, may oppose prevailing sexual mores, as may those who, though not necessarily handicapped or abnormal in a clinical sense, have sexual requirements that are contrary to the norms. These groups provide evaluational support, facilitate recruitment to the role, and insulate members against the sexual mores of the larger society (Hooker 1956).

Social movements concerned with sex have sought revision of sexual standards, of the laws supporting them, and of the means of enforcing them. Corruption in systems of police regulation of prostitution led to the formation of the International Federation for the Abolition of State Regulation of Vice in 1875. The World League for Sexual Reform on a Scientific Basis, perhaps the most extensive such group, was an outgrowth of the Institute for Sexual Science founded by Magnus Hirschfeld in Germany in 1929. It attempted to abolish antisexual taboos, establish a philosophical basis for sexual freedom, and provide education in the form of lectures and clinical advice. The institute was closed by the Nazis, and the world movement collapsed a few years later. Wilhelm Reich, who criticized Hirschfeld for attempting sexual reform within the framework of capitalist society, established the Socialist Society for Sexual Advice and Study in Vienna in 1928 to "defend the rights of children and young people to their natural love."

### Sex and social institutions

The nonerotic components in an eroticized role may link it with a pattern of roles constituting an institution. Historically, eroticized roles have been part of the fabric of economic, political, religious, familial, and other institutions. At certain times, a particular institution, such as the church in Christian society, may exclude the erotic component from its roles and influence its place in the roles of another institution, especially the family.

**The family.** Social movements to reform sexual mores ordinarily protest the family's monopoly of the legitimate eroticized role. The eroticized role is universally legitimated in the family, and in modern Western society it is legitimated only in the family. However, actual behavior is at variance with this official standard. In the Kinsey samples, 50 per cent of the females and 85 per cent of the males with a high school education reported that they had experienced premarital coitus. Nearly half of these females had experienced coitus with a man other than their fiancé. Moreover, by the age of forty nearly 26 per cent of the females and 50 per cent of the males had engaged in extramarital coitus.

Increasing opportunities for premarital and extramarital coitus accompany the greater mixing of the sexes in the educational, occupational, and social worlds. Legal control of premarital intercourse in American society is generally enforced more strictly in the case of younger participants.

Adultery is grounds for divorce in all states. To the extent that coitus takes place outside of marriage the procreative aspect declines in significance. For example, Malinowski (1929) thought that the Trobriand Islanders, who have very permissive sexual mores, did not appreciate the connection between coitus and pregnancy, although it is more likely that, while aware of the connection, they were not much interested in it. Discussions of contraception reveal some tensions aroused concerning nonprocreative coital meanings, since contraceptives are not simply designed to prevent conception but to do so while coitus continues.

**Sex and religion.** Sexual behavior has been interwoven with religion from earliest times. Religion's general concern with fertility involves it in the procreative aspect of sex, and this concern may even become pervasive, as, for example, in the Indian *lingam* cults. Furthermore, sexual energy itself may play a role in religious worship. Scott (1941) concluded that phallic worship originated in the pleasure associated with coitus and not in any clearly conceived notion that intercourse would produce children. Sex as worshipful, expressive communication with a supraindividual force is illustrated by the activities of temple prostitutes in Babylon. Krafft-Ebing (1886) argued that religion and sex could replace one another, since both display a similar scope and quality of excitement at their peaks and both can degenerate under pathological conditions into cruelty. Religious mystical roles may contain an erotic compound in both the Western and Eastern traditions. On the other hand, the cases of the sacerdotal celibate, the religious hermit, or the penitent abstainer illustrate religious exclusion of the sexual component.

Religious considerations affect recruitment to eroticized roles in other institutions. Thus, rules of exogamy and endogamy are generally supported by religious sanctions. Religious sanctification of marriage or the withholding of that sanctification affects the recruitment of coital partners. Moreover, religion may contribute to the isolation of the sexes by separating them in worship and by excluding women from sacred precincts.

Religious devotion is negatively associated with participation in nonreligious eroticized roles in the United States. The frequencies for all sexual outlets, except for marital coitus, decrease with increasing devoutness (Kinsey et al. 1948; 1953). This association seems to hold in France as well (Institut Français . . . 1960).

**Sex and the polity.** The relation of sexual behavior to the nature of the state and politics has long been of popular concern. The literature on

court ladies and on espionage has described the impact of eroticized roles upon political roles. Sorokin (1956) asserted that sexual overindulgence debilitates the entire society. Krafft-Ebing (1886) saw a two-directional relation, in which, on the one hand, sexual excess undermines the props of society and, on the other hand, the collapse of society produces sexual aberrations.

Utopian schemes have included recommendations for control of eroticized roles. Unwin (1940) proposed that, in his new society, Hopousia, there be two kinds of marriage: alpha marriage, which would be monogamous and preceded by prenuptial continence, for those who would achieve, create, and lead, and beta marriage, which may be terminated at will and would not require prenuptial continence, for those who do not aspire to social position. Unwin's thesis is grounded in the concept of energy sublimation. In John Humphrey Noyes' Oneida community, a cooperative colony founded in 1848, extramarital "coitus interruptus" was permitted, on the ground that sex is a way of communicating the meaning of intimate friendship.

The acquisition of political power by men usually implies an access to more women. For example, in Bedouin society, a tribal chief is more likely to be polygamous and to retain concubines than is a less powerful member of the tribe. In Europe, royalty as well as the economically powerful have been able to keep mistresses. Conquest has generally implied access to the women of the conquered society, either by rape, by capture, or through the woman's desire to consort with the powerful.

**Sex and the economy.** Sex has a place in the economy both as a marketable commodity and as a component affecting the marketability of nonsexual commodities. Thus economic value can be derived from sexual value. For example, prostitution involves an economic-sexual exchange of this character; the economic exchange ramifies beyond the prostitute and her client to include the pimp who recruits the client, the madam who supplies facilities for the act, and, perhaps, the police who protect all of them from the law. In the case of marriage, the economic-sexual exchange is embedded in a wider set of family and community relations. Sexual role performance consumes facilities, goods, and services, and thus industries emerge around the provision of facilities for recruitment to the eroticized role and for enactment of that role. These range from the provision of meeting places, such as dance halls; the publishing of pornographic, scientific, artistic, and guidance manuals; the supply of pharmaceutical and me-

chanical contraceptives; and the letting of places, such as a motel room or brothel, for consummating the sex act.

Sexual value may be derivative from economic value as well. For example, sexual jealousy, rather than being an innate emotion, may be related to views of women as property. Jealousy is then an anger aroused when property rights are violated. A norm of premarital chastity may also be related to marketability (Nemeček 1958).

Reich (1930), using syncretistic Marxian-Freudian "sex-economic" concepts, described an interplay between sexual and economic norms. He reasoned that since psychic structure is created by social structure and the core of psychic structure is the sexual function, sexual function is controlled by social structure. Social structure is constituted by the "modes of production," including the interpersonal relations of production. These relations affect sexual needs, among others. They also influence concepts of life, morals, and philosophy—that is, ideology—and so influence sex norms. Classes standing in different relation to the "modes of production" will differ in their sexual needs and norms. The dominant political minority imposes its ideology in general, and its sexual ideology in particular, on a population. According to this view, the subordinate population thus has sex needs derived from its own class position while being subject to the sexual ideology of another class. It should be noted that Kinsey's findings do not support Reich; Kinsey and others (1953) found little relation between the parental occupational class and the incidence of various sexual behaviors.

### Research methods

Methods of social and psychological research developed in other areas have been used to ascertain frequencies of sexual behaviors as well as social and individual meanings associated with that behavior. Questionnaires (Christensen & Carpenter 1962) and interviews (Kinsey et al. 1948) have both been used to elicit such information. Protecting the anonymity of the respondent and establishing the scientific legitimacy of the interviewer are salient bases for rapport during an interview. To maximize the validity of responses, the interviewer must avoid making the respondent feel guilt, anxiety, or defensiveness. Direct questions should be asked with no defensiveness or apology on the part of the interviewer, and terminology should be adapted to the social-class level of the respondent. The inquiry should begin with matters that do not provoke anxiety, such as age, and then proceed to items which are sexual but for

which the individual does not feel responsible; thus the interviewer would ask about spontaneous orgasms before asking about masturbation. The fact that anxiety associated with each type of behavior differs among culture or class groups and between the sexes affects the ordering of the questions. For example, homosexuality is less frightening than masturbation for females in American society, while the reverse is true for males; thus, in interviewing females, questions on homosexuality precede those on masturbation, and the reverse order is used for males. As a practical procedure one might request the age at first orgasm, then ask for its source and, if this is not too anxiety-provoking, trace this source through the years. By asking when he first experienced each type of behavior, the burden of denial is placed upon the interviewee. Kinsey's interviewers severely censured any subject suspected of giving a dishonest history.

Kinsey correlated the frequencies of each source of outlet—masturbation; premarital, extramarital, and marital coitus; homosexuality; and animal contacts—with demographic factors such as national origin, marital status, age, education, occupational class, rural or urban residence, religious affiliation, and religious devoutness, among others. Intrapsychic meanings of sexual behavior have been studied by correlating projective test responses with the frequencies of behaviors. The Rorschach test has been used to reveal body image (Fisher & Cleveland 1958), the Thematic Apperception Test to uncover feelings of guilt associated with sex (Leiman & Epstein 1961), and a combination of the Thematic Apperception Test and the House-Tree-Person Test to obtain data about castration feelings or feelings of phallic inadequacy for psychoanalytic interpretation (Hammer 1957). Anthropological field methods, employing observation and informant interviews, have been used to gain information about both the occurrence of behaviors and their meanings (Malinowski 1929). Observational methods supply data on systems of communication and interaction that are necessary for an analysis of the social organization of sexuality (A. J. Reiss 1961). The Human Relations Area Files, containing field reports on many societies, have been used to exploit the advantages of both field observation and correlation methods (Murdock 1949). Attitude questionnaires have been used to obtain information on ideal prescriptive norms, as has content analysis of newspapers, radio, and plays (A. Ellis 1954).

The fact that the various sexual behaviors may be ordered along dimensions of greater or lesser intimacy or greater or lesser acceptability has been

exploited to construct scales. Podell and Perkins (1957), for example, developed a Guttman scale for ordering types of sexual experience, and Ira Reiss (1964) developed a refined Guttman scale for a study of standards of sexual permissiveness.

### III

#### SEXUAL DEVIATION: PSYCHOLOGICAL ASPECTS

One premise of psychoanalytic doctrine is that the general developmental process of childhood includes psychosexual development. It may be taken as a general premise of all growth, physical and psychological, that at any one stage of devel-

opment the organism's current growth status and future potential is determined by (1) what it began with, (2) what has been added or subtracted in the interim, perhaps irreversibly, and (3) the growth-facilitating or growth-impeding environment that it may meet. Thus, at the moment of conception, growth status and potential is determined by both the quantitative and qualitative aspects of the genetic code of information, supplied half by the mother, half by the father, and by the intrauterine environment in which the fertilized egg exists. The intrauterine environment may prove hostile mechanically, metabolically, or because of the invasion of foreign organisms, viruses for example. The embryo itself may be its own enemy, as when a particular developmental phase or system fails, with subsequent deleterious effects on another phase or system. For example, if the testes differentiate imperfectly in a genetic male, then the fetal testicular secretions fail, with the result that the anlagen of the external genital morphology develop as either completely or partially female, depending on the degree of testicular failure. Contrarily, in the case of a genetic female, if the fetal adrenal cortex functions erroneously, so as to produce an excess of androgen in the place of expected cortisone, then the anlagen of the external genitalia will masculinize in their development, even to the point that the genital tubercle becomes a fully formed penis instead of a clitoris.

#### Principle of the critical period

Both of the foregoing examples of an error in embryonic sexual development illustrate the principle of the critical period, that is to say, that period in the development of some system or function when the organism passes from a neutral or undifferentiated stage to a differentiated one. It is during this critical period that development is vulnerable to interference and deflection, which, if they occur, will leave a permanent residual in structure or function. The further development of the organism will then in some degree be determined by, or influenced by, the outcome of the critical period.

Effects of atypical early experiences. The concept of the critical period applies not only to morphologic and prenatal development, but to behavioral, psychological, and postnatal development as well. In behavioral science, the European animal ethologists were the first to observe that patterns of behavior, including sexual behavior, can be experimentally changed during a critical, developmental learning period, and thenceforth

this deviance becomes relatively fixed. In other words, particular atypical experiences may interfere with or deform the genetic, hormonal, or neural norms of behavioral development otherwise expected.

The justly famous experiments of Harlow (see Money 1965a, chapter 7) on the macaque monkey are a case in point. The experimental monkeys showed that opportunity to play with age-mates in early childhood was a developmental prerequisite to the achievement of normal copulatory ability in adolescence. Depriving the infants of childhood play, combined with depriving them of interaction with their mothers by rearing them with dummy mothers made of wire covered with a piece of towel, had particularly adverse effects. Such doubly deprived animals were unable to adapt to the motions of mating and to effect sexual intercourse even when paired with mates selected for experience and gentleness. Those few females in whom pregnancy was finally achieved were incompetent to mother their own young. They neglected and injured them, sometimes cruelly. Other aspects of their behavior, in general, also appeared to be grossly disordered.

Another illustrative experiment is that of Birch (1956). Female rats were raised in isolation with a rubber collar or ruff around their necks, which deprived them of the experience of licking themselves or others. They were finally released from their collars to deliver their first litter. Instead of licking the young as they were born, they ate most of them. The surviving 5 per cent were retardedly and improperly retrieved and badly suckled; some were eaten after being carried to the nest. Three survivors of a large litter died of starvation. Their mother had shepherded them under her chin every time they approached her belly to search for a nipple.

Experiments in population density with rats have demonstrated yet another way in which behavioral experience, namely crowding, may induce aberrant sexual and social behavior (Calhoun 1962), affecting even the unborn fetuses and their future behavior, presumably via the maternal endocrine system (Keeley 1962).

The proper understanding of psychosexual development and of erroneous development in human beings requires focusing attention on experience, behavior, and social interaction during the formative years of childhood. In man, perhaps even more so than in lower species, peculiarities and special features of experience during critical periods may change the expected genetic, hormonal, or neural norms of development.

**Hermaphroditism—an example.** Probably the most dramatic illustration of this last proposition is to be found in the psychology of hermaphroditism (Money, Hampson, & Hampson 1957; Money 1961). Human hermaphroditism, for which there are several different etiologies, is conventionally defined in terms of a discrepancy between the gonads (ovaries, testes, or, rarely, ovotestes) and the morphology of the external genitalia. Sometimes the discrepancy may be total, as indicated at the beginning of this article, namely, when the gonads are testicular and the external organs are perfectly female (the syndrome of testicular feminization) or when the external organs are perfectly male except for an empty scrotum, the gonads being ovaries and in proper ovarian position (a rare variant of the hyperadrenocortical syndrome of female hermaphroditism). Most commonly in hermaphroditism, however, the discrepancy between gonads and external organs is incomplete, by reason of the fact that the external organs are themselves imperfectly differentiated as either male or female. In this incompletely state of differentiation, the external sex organs of either sex look remarkably similar: the penis with a urinary gutter instead of a tube and with its orifice near the scrotum can easily be confused with an enlarged clitoris, and the incompletely fused scrotum may pass for labia that have improperly begun to fuse. Because confusion is possible and because medical decisions may sometimes differ, it may so happen that two individuals of identical genetic, gonadal, and hormonal diagnosis are assigned to different sexes.

**Effects of sex assignment.** The expected outcome of such sex assignment is that psychosexual differentiation will proceed to take place congruously with assignment and rearing. Ideally, the external organs will have been repaired surgically as early as possible, so as to conform to the assigned sex. The visible, kinesthetic, and tactile body image is a potent fact in a child's own awareness of his or her gender identity, and the visible appearance of sex is, of course, the ultimate criterion for the gender-role expectancies imposed by most of the people who are significant in a child's life.

Even with delayed genital repair, it has proved possible for psychosexual differentiation to take place in keeping with assigned sex when genetic, gonadal, and hormonal sex are at variance. Incongruous-looking sex organs militate against psychosexual differentiation appropriate to sex assignment, especially when the incongruity is reinforced by some other source of ambiguity such as paren-

tal lack of conviction as to the way they should be rearing their child or open doubt expressed by age-mates. In some instances, doubt may develop in the child's own mind without any clear retrospective indication of its origin.

Ideally, for psychosexual differentiation to be brought to maturity at puberty, assigned sex should not be at variance with hormonal sex and the secondary sexual changes of the body that are hormonally controlled. This ideal can be met in modern endocrinology. Yet, there are occasional untreated cases; among them are cases of hormonal virilization in girls with the hyperadrenocortical syndrome, which is remarkable in view of the intensity of virilization and its early onset before the usual age of puberty. These cases show that the persistence of a feminine psychosexual differentiation is possible despite the hormonal contradiction and its severe handicap to proper adolescent social maturation.

**Crucial variables.** In psychosexual differentiation, the crucial variables, which may in hermaphroditism be independent of one another and may be overridden by the experiential effects of assignment and rearing, are five: (1) chromosomal sex, as determined by actual chromosomal count, (2) gonadal sex, (3) hormonal sex, (4) internal accessory morphologic sex, and (5) external morphologic sex. Psychosexual differentiation itself transcends not only all five of these variables but also the assigned sex in the syndrome of transvestism with transsexualism, which has, therefore, been treated, and not without reasonable success, by surgical, hormonal, and social sex reassignment (Benjamin 1964; Pauly 1965).

To have found rare clinical cases in which the five physical variables can be overridden is not, of course, to have proved that the physical variables do not under other circumstances contribute to, or help determine, psychosexual differentiation. What has been proved is not that psychosexual differentiation is always and exclusively a matter of behavioral and experiential life history but that experiences determined by rearing are far more potent than might otherwise have been expected. Harlow's investigations on the macaque demonstrated, on the one hand, the extraordinary power and permanence of the social-experience factor in preventing psychosexual maturity; but they also led him, on the other hand, to conclude that sex differences in normal macaque behavior antedate childhood experience and learning.

Harlow observed (1962) that the young male monkeys made more threats toward other monkeys, both male and female, than did the young females.

The females' threats, moreover, were reserved primarily for other young females. The young females retreated more often than the males, specifically by adopting the female sexual posture. The young males initiated more play contacts, with playmates of either sex, than did the females; and the males had a monopoly on rough-and-tumble play. With increasing age, the males showed increasing frequency of the male mounting position in their copulatory play. They showed little grooming behavior, which, in adults, is more a characteristic of female than male sexual behavior.

The application of Harlow's method of direct observations and systematic experiments on monkeys is restricted in human beings, as compared with clinical case study, by reason of the usual ethical vetoes on experimental manipulation of the lives of human beings and by the customary taboos imposed on sexual play and the expression of sexual interests in childhood. Systematic experimental attempts to study the development of masculinity and femininity have confined themselves to the secondary data of questionnaires or interviews or to the oblique data of free association, projective tests, and play. Although not thoroughly consistent or definitive, the findings show that psychosexual differentiation varies with age and in some degree is related to family and class differences in child-rearing practices and the emotional quality of the relationship between the child and each parent.

**Sex reassignment.** That there is a critical period in psychosexual differentiation, and that it is early in life, is suggested by clinical evidence, again from hermaphroditism, namely in instances of a change of the sex of assignment (Money, Hampson, & Hampson 1956). It is not difficult for a child under a year of age to adjust to a sex reassignment, provided the parents can also adjust. But the older the child—for example, if he is past the age of learning to talk and is becoming acquainted with the verbal and other signals of gender difference—and the further that psychosexual differentiation has progressed without ambiguity, the progressively less likely it is that an imposed sex reassignment will be successfully assimilated. It thus appears that the establishment of a psychosexual identity and gender role roughly parallels the learning of the native language. The critical period, in which the basic essentials are laid down, is ended probably by the kindergarten age. The remaining years of childhood are years of consolidation until the hormonal changes of adolescence bring psychosexual differentiation to its completed expression in both the subjective

tropins cyclically, as in the female; and it allows mating pattern elements that are chiefly masculine, although they are shared by both sexes, to predominate in childhood.

### Some dimensions of deviance

**Androgen as an organizer.** Androgen is thus implicated as an active organizer of the sexual control system, both in terms of reproductive cycles and sexual behavior. At a critical period earlier in embryonic life, androgen is an active organizer substance without which the internal anlagen of the female reproductive anatomy persist and the anlagen of the external organs feminize (Jost 1958). Nature's primary impulse, in other words, is to make a female. One conjectures a relationship here with the greater vulnerability of the male to disease and death, which would create an unequal sex ratio except for the fact that 106 males are born to 100 females. One conjectures also a connection with the fact that psychosexual disorders have a higher incidence in men than in women, with some of the psychosexual anomalies, like fetishism, voyeurism, and exhibitionism, being to all intents and purposes unheard of in females.

**Sex differences in arousal patterns.** The higher incidence of psychosexual pathologies in the male may be related to a sex difference in erotic arousal patterns. This difference is manifested in the greater capacity of the male to be aroused erotically and genitopelvicly, and to be ready for immediate release, by pictorial and narrative imagery. Such stimuli arouse the female sentimentally to want her lover or husband; but she is dependent on direct tactile stimulation, more than the male, for the arousal of genitopelvic eroticism.

There is some evidence in the psychology of hermaphroditism that the male arousal pattern may be neurally organized under the influence of androgen in fetal life. It will be for further research to determine whether the development of psychosexual pathology in the male may be rooted in part in imperfect or faulty neurohormonal organization at this early period. One thing already quite clear in the evidence of hermaphroditism is that a masculine type of arousal pattern is perfectly compatible with entirely feminine cognitive content and imagery of eroticism that parallels the sex of assignment.

**Arousal stimuli.** Perceptual stimulants to sexual arousal and the reproductive cycle vary with the species. The relation between light stimulation and the release of pineal hormones is being newly investigated in the rat. Olfactory stimuli also are

the subject of important new experiments (Parkes & Bruce 1961), which show, after copulation in the mouse, that odors released by the male regulate the establishment of pregnancy in the female. Acuity of the sense of smell in human females (Money 1965b) is regulated by estrogen and varies with the menstrual cycle. Its relation to other cyclic sexual phenomena or to sexual disorder has not been investigated. Odor may be the agent responsible, in the macaque monkey, for fluctuation in male sexual behavior in rhythm with the female menstrual cycle, as described by Michael and Herbert (1963).

In addition to benefiting from the new neurophysiological techniques, contemporary sex research has also benefited from the new techniques in genetics. These techniques have enabled researchers to establish the presence (female) or absence (male) of the sex-chromatin mass (Barr body) in the nucleus of the body's cells and to photograph, measure, and count the actual chromosomes in cells. The relevance of the new findings to the theory of psychosexual pathology has been chiefly negative: gross chromosome defects are not demonstrable in the majority of psychosexual disorders. A partial exception may exist in the case of Klinefelter's syndrome. Affected individuals are phenotypic males with an extra X chromosome. There appears to be an unusually high incidence of psychopathology, including sexual disorders, that develops in association with the syndrome (Money 1963a). Among the sexual disorders are homosexuality and transvestism (Money & Pollitt 1964). Otherwise genetics cannot be directly implicated in psychosexual ambiguity (Money 1963b).

Disorders of sexual psychology express themselves in full in adolescence after the advent of hormonal puberty brings erotic functioning to maturity. It is probable that the majority of such disorders have their initial origins in faulty psychosexual differentiation persisting from early childhood. Later error or regression of differentiation are also possible, as is simple arrestment in psychosexual growth.

Faults, errors, regression, and arrest of development have, on the one hand, a chronologic origin and, on the other hand, an etiologic origin. The chronologic origin may fall within a critical period, with resultant immutability or refractoriness to change. The etiologic origin may be single or multiple. An etiologic factor may by itself represent only a potential vulnerability to psychosexual disorder, materializing only when in combination

with another factor or factors. Thus a genetic vulnerability may materialize only when the behavioral environment conspires appropriately. Etiologic considerations include genetic, gestational, metabolic, nutritional, toxic-infective, traumatic, behavioral-experiential, and social-interactional factors.

#### IV

#### SEXUAL DEVIATION: SOCIAL ASPECTS

Deviance in general, and sexual deviance in particular, presents the scientist with extremely difficult problems of definition and analysis. Sexuality is, perhaps more than any other aspect of human behavior, mingled with moral imperatives, conscious fantasy, and unconscious desires, all of which combine to trouble even most scientific ob-

against which strong sanctions are invoked, that does not seem to be learned in recognizable deviant social structures and that does not have a socially organized performance system.

**Functional deviance.** Masturbation and premarital coitus are primary examples of behavior that is generally defined as deviant but that does not involve the application of sanctions unless the perpetrators are, by some mischance, apprehended or there is some untoward consequence, such as pregnancy or venereal disease. These forms of behavior may be described as "wrong but normal." There is considerable class variation in the incidence and frequency of masturbation and premarital coitus, with the former important among middle-class males and the latter among lower-class males. Solitary masturbation is not against the law; premarital coitus may be, especially if either party is legally a minor, but even so prosecutions are comparatively rare.

The perceived utility of masturbation as a male adolescent sexual outlet with few social consequences in comparison to coitus may account for the decreasing stigma attached to it. It seems to be related to other behavior defined by social class and characterizes males who assume middle-class occupational roles (Kinsey et al. 1948, chapter 10). Premarital coitus is culturally valued for males especially within the pro-masculine lower-class culture, accounting for its prevalence and the lack of invoked sanctions (I. Reiss 1960; Whyte 1943). Both masturbation and coitus are class-linked and seem to be the most appropriate responses to the impact of the sexual drive after puberty in the male. For females premarital coitus is connected with impending marriage and a love relationship; thus, the behavior is defined as proper in a situation-specific way. Masturbation in females seems to have no class linkages at all. In general these activities have a smaller incidence and a lower frequency among females than among males, possibly because of both hormonal differences and differences in socialization.

**Deviant subcultures.** The second type of deviant sexual behavior is that which involves supportive social structures either for the purpose of entry into the system of behavior or for the maintenance of the individual in the behavior. This type of behavior comprises homosexuality and prostitution. It is only female prostitution that has all the elements of a deviant subculture similar to that of drug addicts or juvenile delinquents (Davis 1961; Kinsey et al. 1948, chapter 10). In this situation the stigma for the sexual behavior is attached to the prostitute, and the legal sanctions for

the behavior are leveled primarily against her, secondarily against the abetting persons (pimps, madams), and exceedingly rarely against the customers or against agents of law enforcement who may condone her activities. Prostitution develops organized forms primarily because of its commercial aspect and because of the character of the enforcement program that is designed to control it.

For the most part, recruitment of individuals for homosexual experience does not occur through a social system organized for that purpose. The majority of persons who come to conceive of themselves as homosexual do so on the basis of readying experiences early in life that are linked to secondary reinforcements in puberty. Unfortunately, studies of the etiology of homosexuality have been most unsatisfactory in their attempts to locate the crucial early experiences that are salient (Money 1963). Some etiological studies have focused on biological and especially genetic factors, sometimes mediated through hormonal anomalies. But even though there have been some studies of twins (Kallman 1952; 1963) and some work has been done on hormonal factors (Kinsey 1941), the most persuasive discussions of early factors in the development of a homosexual commitment have been couched in the psychoanalytic tradition or in certain variants of it (Society . . . 1962; Ovesey 1954). The psychoanalytic tradition locates the origins of homosexuality in pathological versions of parent-child relations in which the mother provokes her son's sexual interest and in consequence burdens him with an anxiety about incest with which he cannot deal. As a result his relations with females are blighted because of his fears of paternal revenge for his incest, which remains forever unconsummated. Other explanations in this tradition are less metaphorical in their language but still focus upon seductive mothers, detached fathers, lack of a male figure in the home, and the like. Unfortunately the bulk of the populations who have been the source of the data in these reports have been examined in the course of psychotherapy or other treatment, creating a situation in which pathology and homosexuality are inextricably confounded.

Psychological research into homosexuality has also maintained a determined concern with the etiological question and with developing instrumentation that might successfully distinguish between the homosexual and the heterosexual on the basis of either manifest items or latent items that are presumed to be indicators of homosexual commitments (see, for instance, the psychometric indices of masculinity and femininity used by Brown 1958;

Hooker 1957; 1958; Dean & Richardson 1964; Freund 1963).

During the pubescent years there is a good deal of minor homosexual experimentation that accounts for nearly all of the homosexual activity of the predominantly heterosexual portion of the population. Thus, it can be predicted that about one in three of all males born in the United States will at some time have a homosexual experience to the point of orgasm; however, about 85 per cent of those having such experience will do so only in their adolescent years. Among females the proportion who ever have a homosexual experience will be somewhat smaller, but once again most of them will confine the experience to adolescence (Kinsey et al. 1948; 1953). The factors that distinguish those who go on to adult homosexual commitments from those who experience homosexual acts only as transient parts of adolescent development are still unknown. However, it is known that males often develop strong sexual interests in other males without knowing that there is such a thing as homosexuality. (This process occurs more frequently in specialized sexual interests such as transvestism and fetishism.)

The realization of being homosexual occurs in a variety of ways: sometimes through processes of introspection, sometimes through falling in with other homosexuals who act seductively, and sometimes through sexual contacts with other males who finally become defined as homosexual. It is after the point of conscious admission that one is a homosexual—an admission that ranges from the traumatic to the delighted—that the search for sexual partners begins. This search usually requires entry into the world of homosexual bars, development of the argot of homosexual life, and gradual learning of the modes of approach and retreat that are related to the satisfaction of sexual needs. Study of this zone of the homosexual's adjustment is beginning to result in a literature that suggests that adult homosexual commitments are not re-enactments of early pathological relations between parents and children. These studies have begun to outline the processes of adult socialization that are involved in the development of the homosexual commitment. There now also exists a literature on particular aspects of the homosexual life (Hooker 1966; Leznoff & Westly 1956; Achilles 1967).

The extant literature is nearly exclusively concerned with the male homosexual; the literature on the lesbian is both scanty and scientifically inadequate. In general, discussions of the lesbian tend to focus on the similarities between male and

female homosexuality and to see one as the mirror image of the other—that is, to see male homosexuals as imitations of females and female homosexuals as imitations of males. A more satisfactory view, however, is to see female homosexuality as continuous with normal female sexuality (Simon & Gagnon 1967; Ovesey 1956).

Not all homosexuals are regular members of the homosexual community and many of them never involve themselves in this social milieu at all. It is difficult to determine whether or not a more intensive or a more detached relationship to the community is more helpful in the homosexual's personal and social adjustment. The maintenance of female homosexuality occurs more often outside the community context than does homosexuality among males (Simon & Gagnon 1967).

The development of homosexual contacts among prisoners in penal institutions is more like an articulated system of introduction to homosexual experience than is homosexual development in the free community. Homosexual behavior in prisons ranges from the careful seduction, in adult male institutions, of a weaker male by an aggressive male (involving money and protection from the latter in exchange for the sexual cooperation of the former, and often leading to "marriage") to the "extended family" systems observed in juvenile female institutions and the homosexual "bringing out" in female penitentiaries (Lindner 1948; Sykes 1958; Halleck & Hersko 1962; Lamberti 1963; Ward & Kassebaum 1965; Giallombardo 1966).

**The antisocial deviant.** The third type of deviant sexual acts to be considered are those most specifically prosecuted by law-enforcement agencies; they involve aggression, youth, close kin relations, and public disturbance (a typology suggested both in Wheeler 1960 and in Indiana University 1965; see pp. 1-13 for the classification of sex offenders). Most of these acts are committed by individuals whose behavior is the result of needs developed outside any subcultural or deviant training ground composed of other persons oriented toward the same behavior. The origins of heterosexual pedophilia, for example, seem to lie in the incapacity of the male to establish any meaningful relationship with an adult female or in many cases a failure to find any sociosexual outlet at any level of psychological involvement. The pedophile resorts to children because the difference in age gives him a sense of power over them as well as the hope that he will meet with an uncritical reception. There is no social support for the act either before or after its occurrence. The individual has the latent capacity to commit the act without any

social support, and at the intersection of the appropriate forces (aging, alcohol, fatigue, emotional stress) a sexual contact with a child occurs. The model of the behavior that seems to be most useful is that of the releasing mechanism. The pedophile has learned in childhood a certain set of responses that gives him the potential for the act as an adult. Under the appropriate circumstances the potential is realized.

Other sexual acts of the third type that have some of the aspects of pedophilia are homosexual pedophilia, exhibitionism, compulsive peeping, and sex offenses involving incest and the use of force. In the cases of peeping, assaultive offenses, and incest there are certain complicating social or cultural factors. Peeping and the use of minimal aggression in sexual relations are not necessarily viewed as abnormal or deviant. The act of peeping is something that many males have performed when confronted by a lighted unshaded window; however, for the impulse to invade and dominate the sexual life of the individual to such an extent that he must seek out windows in which to look suggests that more than a simple heterosexual interest is involved. A certain amount of aggression by males is expected in the process of sexual exploration in Western culture, and it is clear that excessive force is used more frequently than is reported to the agencies of law enforcement. This is predominantly a lower-class phenomenon, but not totally so, since there is evidence for its occurring among college-level males as well (Kirkpatrick & Kanin 1957). There are indications that those college-level males who do use force have certain other characteristics that differentiate them from males who do not use force. The aggressive male is commonly responding to his own needs rather than to the interactional situation in which he is involved. What may be involved is a blunting of the capacity to recognize negative signs displayed by the female, either as a function of the male's specific personality characteristics or as a function of his sexual excitement.

*Incest.* The problem of sexual contact between relatives is confined primarily to father-daughter contacts and to a lesser extent to those between brothers and sisters and between cousins. The last two are usually transitory childhood contacts or those that take place just after puberty, and in the case of brother-sister incest they may be made more complicated by the presence of mental deficiency. Father-daughter contacts are most prevalent in rural, or rural-origin, families. The families in which such contacts occur commonly are extremely disorganized families in which the father

converts the daughter into a source of sexual and often pseudo-marital relations (Kaufman et al. 1954). Mothers in these families retreat from the center of the family life, and only if the daughter is quite young does the mother inform the police. With very young daughters the offense often has elements of pedophilia.

*Sex-offense rates.* A useful point to be made about deviant behavior of this third type is that over long periods of time it represents a relatively stable proportion of all offenses known to the police, of all persons arrested, and of all felons in penal institutions. In addition, the rates per hundred thousand in the population have remained stable for many years. The stability of these rates indicates that disturbed and disorganized families represent a rather constant source of individuals who grow up with strategic weaknesses in their character structures and thus become sexual offenders. The rate of increase in the number of such persons, however, does not exceed the growth rate of the population, indicating that the roots of these kinds of deviant acts are in the family, as the basic unit of social organization, rather than in secondary social structures.

As can be seen from the foregoing discussion, the forms of sexual behavior that are approved arise from sources very similar to those from which the forms called deviant arise, and the margins between one and the other are sharp in moral evaluation but vague in fact. The general situation of sexuality in this society may be best described as that of pluralistic ignorance, a condition of noninformation and misinformation that serves to direct (or misdirect) a powerful drive.

For the vast majority of deviant sexual acts, negative sanctions are frequently expressed but only sporadically enforced. For a smaller proportion of acts, deviant behavior involves recognizable social organization that serves either as a learning structure or as a performance structure for the development and maintenance of the behavior. Finally, for a very small proportion there seem to be no social structural components to the behavior, either for its development or for its continuation, and its origins seem most likely to be in early familial life, as was explained above.

With the general absence of mediating social structures between the original development of sexual capacity in childhood and the performance of sexual roles in adulthood the conditions described above are not surprising. Sexual roles are worked out on an individual basis with a general incapacity to share and reformulate very large portions of the

sexual experience. Since there is a high premium on silence in sexual matters, there is rarely an opportunity for social checks on deviant impulses, nor does there exist any system by which the behavior of individuals, if it varies from the rigid normative standards, can be examined in terms of the behavior's relevant social and psychological meaning. Of all of the areas of deviant behavior, it is sexual deviance which most strongly maintains its "individualistic" character.

## V

## HOMOSEXUALITY

Homosexual practices are among the most ancient manifestations of human sexuality. Abundant evidence for this fact is found in both the religious and the secular literature of the oldest civilizations and in their graphic art as well. Social attitudes in different cultures apparently varied then, as now, from strong condemnation of all homosexual practices to tolerance or permissiveness for some. From the beginning of the Christian era in western Europe ecclesiastical and secular law sought to prevent, control, and eradicate homosexuality by means of severe moral and legal condemnation. By the late nineteenth century, legal penalties were less severe as a result of humanitarian reform, but moral and religious censure had not diminished. That the scientific study of homosexuality began in this period of western European history, and in this cultural climate, is a tribute to the scientific and humanitarian interests of physicians, particularly such pioneers as Richard von Krafft-Ebing,

Sigmund Freud, Havelock Ellis, and Magnus Hirschfeld. Their theories were largely concerned with etiology and were based on clinical observations and influenced by developments in the biological sciences, including evolutionary theory. Although by this time cross-cultural observations of homosexuality were also accumulating, together with the rudiments of a general theory, they had little effect on the mainstream of research, which continued to focus on the etiology of homosexuality among individuals of Western culture.

Increased research on homosexuality in Western countries since World War II has been coupled with more open discussion of the subject. Although there is no reliable evidence that the incidence of homosexuality is increasing, some forms of it are more socially visible. In part, this may be accounted for by the publicity given to scientific investigations of homosexuality and to discussions of the controversial social, legal, moral, and mental health issues related to it. Emergent homosexual "communities" in large urban centers and "homophile" organizations openly protesting public policy further contribute to this heightened visibility and increased public awareness. These developments reflect radical changes in the attitudes of the public and of homosexuals, in the social character of homosexuality, and in the volume and focus of scientific research.

Homosexuality (*homo-* derives from the Greek root meaning "same") includes an extraordinary diversity of dyadic relations and of individual mental states and action patterns. The patterns of social organization that develop when homosexuals seek each other out also vary greatly. Because of this diversity, "homosexuality" is an ambiguous term with many meanings. Some investigators, such as Ford and Beach (1951), limit the term to overt sexual relations between individuals of the same sex. For others, notably Kinsey and his associates (1948; 1953), the degree of psychic arousal and the frequency of overt sexual response to individuals of the same or opposite sex determine ratings on a heterosexual-homosexual continuum that ranges from exclusively heterosexual to exclusively homosexual, with several intermediate ratings. Investigators with a clinical perspective (see, for instance, Marmor 1965, p. 4) frequently stress motivational and subjective aspects of erotic preference as criteria for defining persons as homosexual; overt behavior is considered as of secondary importance. In the social perspective of homosexual subcultures, the defining criteria may be shared understanding of sexual preferences for members of one's own sex and participation in social activity

centered on the search for, and interaction with, these individuals (Goffman 1963, pp. 143-144). Thus, it is clear that "Who is homosexual?" and "What is homosexuality?" are very complex questions, clarification of which would be a lasting contribution to social science.

Research on homosexuality is also of major significance for the light it throws on the relation of social structure and cultural norms to patterns of human sexuality; on the origins, development, and essential features of normal and abnormal personality; on masculinity and femininity; and on social deviance and deviant subcultures.

### Etiology and determinants

In those Western societies that define homosexuality as deviant, there are four major theoretical issues concerning the etiology and determinants of persistent or predominant adult homosexuality. (1) Is the human organism psychosexually neutral at birth, so that learning processes determine homosexual object choice in adults, or are there "inherent sexual predispositions" (Diamond 1965, p. 168) which selectively influence the effects of learning? (2) What is the nature and content of the learning processes by which homosexual object choice develops? Is the appropriate developmental model a deviant role or a personality system with intrapersonal traits, motives, and gender identifications incompatible with the social-sexual capabilities and self-other expectancies of adult relations with the opposite sex? Does positive conditioning of sexual responses to persons of the same sex, or negative conditioning to persons of the opposite sex, or a combination of both, account for homosexuality? (3) Are particular periods in the developmental process, such as early childhood or adolescence, critical for homosexual object choice? (4) Are parent-child relationships in the nuclear family crucial in determining whether an individual becomes homosexual, or are peer relationships in childhood and adolescence, and deviant subcultures in adolescence and early adult life, of equal or possibly greater importance? These four issues are highly controversial and cannot be resolved by the research evidence currently available. A brief historical review of some of the major studies will illustrate differences in theoretical assumptions, in methodological approaches, in findings, and in conclusions, and it will indicate important areas for continued research.

**Theories of homosexuality.** Early theorists stressed the importance of biological predispositions as determinants. Krafft-Ebing (1886) theorized that homosexuality was produced by a

dominance of opposite-sex brain centers (female centers in males or vice versa) or that it was a hereditary disease. Freud (1905) postulated constitutional bisexuality as one of the biological predispositions which, together with early learning experiences or fixations, determined homosexual object choice. The major studies of biological predispositions have focused on genetic, chromosomal, and hormonal anomalies or dysfunctions. Comparisons of predominantly homosexual and heterosexual males with respect to chromosomal abnormalities have resulted in negative findings. In several studies, maternal age and birth order of homosexuals in a sibling series were significantly later than in control groups of heterosexual men. The degree of concordance of homosexuality in identical male twins appears to be significantly higher than in fraternal twins (for a review of these studies, see Pare 1965). The evidence is controversial but suggests that genetic mechanisms may be important. Significant progress could be made by replicating the studies of twins, birth order, and maternal age and by an intensified search for genetic determinants. Homosexual object choice in adults is not affected by hormone therapy and differences between the endocrine systems of homosexuals and those of heterosexuals have not been reliably demonstrated (Perloff 1965). As more accurate techniques of measuring hormonal activity develop, continued research may be valuable. A potential contribution of biological factors to human homosexuality is suggested by recent studies of animals, in which the location and functions of sex-specific behavior centers in the brain have been demonstrated (Krafft-Ebing may be vindicated!). Studies at the infrahuman level have also demonstrated that hormones injected prenatally produce effects on adult sexual behavior (for a review of these studies, see Diamond 1965). Thus, specific biological predispositions may be crucial variables, interacting with psychological and cultural variables, especially in producing the highly feminized males and masculinized females often referred to as "inverts."

The experiential determinants emphasized by classical psychoanalytic theory are pathogenic parent-child relations and failure to successfully resolve (unconsciously) the vicissitudes of the three basic phases of libidinal and object-relations development in the critical period of infancy and early childhood. Some revisions of psychoanalytic theory reject constitutional or psychological bisexuality and emphasize ego adaptations to environmental difficulties. With few exceptions, however (see, for instance, Thompson 1947; Sullivan

1953), pathogenic relations with parents in early childhood are assumed to be the crucial determinants, although individual patterns of behavior are subject to modification during adolescence. (For a review of psychoanalytic theories, see Society of Medical Psychoanalysts 1962, chapter 1.)

This theoretical assumption currently relies for empirical support on conflicting and controversial data derived largely from comparing the life histories of adult homosexual and heterosexual males. Freund and Pinkava (1961) carefully tested clearly formulated hypotheses concerning parent-child relations and homosexuality by comparing interview data from male homosexual patients in a psychiatric hospital with similar data from two contrasting matched groups: neurotic heterosexual patients in the same hospital and nonpsychiatric patients. They found no significant differences between these groups with respect to the dominance, control, or decisive influence of either parent in the family. Relations between homosexual sons and their fathers were more "disturbed," a finding tentatively interpreted by the authors as secondary to, rather than a cause of, homosexuality, since the disturbance appeared to be mainly on the son's side of the relationship. Reports of greater conflict between parents of homosexuals signified a lack of tolerance by their sons for marital conflict rather than greater incidence of actual conflict. Bieber and his co-workers (see Society of Medical Psychoanalysts 1962) compared questionnaire data provided by psychoanalysts concerning their homosexual and heterosexual patients. Some differences between patient-mother-father, mother-son, and father-son relationships in the contrasting groups were statistically significant. The authors concluded that the chances of becoming homosexual or of developing severe homosexual problems appear to be high for any son who is exposed to the combination of a "close-binding-intimate" mother who dominates and minimizes her husband, and a father who is detached or hostile (p. 172). Schofield (1965) compared interview data obtained from six matched groups: (1) homosexual and pedophilic prisoners convicted of homosexual offenses, (2) homosexual and heterosexual patients who were in psychiatric treatment, (3) homosexuals and heterosexuals who were neither in treatment nor in prison. The proportion of individuals from disturbed home backgrounds was similar in each matched pair of groups; it was lowest in the non-treatment-prison groups and highest in the patient groups. The proportion of individuals who reported possessive, overprotective, or dominant mothers

and poor or nonexistent relations with fathers in childhood was larger in the combined homosexual groups (pedophiliacs excluded) than in the combined heterosexual groups (p. 105).

The evidence from these and many similar studies does not support the assumption that pathological parent-child relations are either necessary or sufficient antecedents or determinants of adult homosexuality. The evidence does indicate, however, that some forms of familial pathology appear to be associated with increased vulnerability of some individuals to homosexual development, and it suggests that psychopathology is more frequently associated with homosexuality in these individuals. Longitudinal studies could now be designed for the testing of hypotheses specific to the differential effects of variable combinations of parent-child relations on the development of adult psychosexual patterns. The potential contribution of such studies is very high.

Empirical evidence that determinants in adolescence are critical for adult homosexuality is fragmentary. The theoretical rationale for this assumption is that one of the major developmental tasks of adolescence is the achievement of a stable psychosexual identity. An extensive body of clinical-theoretical literature emphasizes the adolescent period as critical for the resolution of intrapsychic psychosexual conflicts originating in infancy or early childhood (Society of Medical Psychoanalysts 1962). Sullivan (1953) stressed very close and intense preadolescent friendships with peers of the same sex as one of the essential conditions for heterosexual development and the separation of lust and intimacy "dynamisms" as one precondition of adult homosexuality.

Assuming that the human capacity for homosexual as well as heterosexual response is a basic part of the mammalian heritage, Kinsey and his associates (1948) suggested that cultural pressures and social conditioning may determine the final object choice. That adolescence may be a critical period for males is indicated by (1) the existence of a high positive relation between the early onset of adolescence and frequency of homosexual activity during adolescence and later life (*ibid.*, p. 630) and (2) occurrence of the peak of sexual activity between ages 16 and 20. Among females, however, no consistent relation was found between homosexual activity and early onset of adolescence (Kinsey et al. 1953, p. 462), and the peak of female sexual activity occurs in the late twenties (*ibid.*, p. 759).

Group norms and peer relationships in adolescence may determine the relative frequencies of

heterosexual and homosexual patterns in adults by affecting their self concepts, sex role expectations and performances, and notions of what constitute the boundaries of permissible behavior. Reiss (1961) found that members of a group of male juvenile delinquents who engaged in sexual acts with adult homosexuals did not define themselves as homosexuals and did not continue homosexual activity as adults. Group norms defined the limits of permissible sexual activity, rules of payment, frequency of contact, and derogatory attitudes toward homosexuality. Conversely, late adolescents or young adults who participate in homosexual cliques or informal homosexual groups may progressively redefine homosexual behavior in positive terms, defining themselves as homosexuals in the process, and thus beginning a homosexual "career" (Hooker 1965a, pp. 90, 101).

Adult homosexual roles may be formed by a continuous process of social-sexual learning, from early childhood to adolescent and early adult life. Self-other interactions, including overt sexual activities, in deviant socially marginal pairs or groups of peers of the same sex, may be critical determinants of motives, self concepts, sex role expectations and abilities, and performances that are congruent with deviant and homosexual roles and incongruent with heterosexual roles. At critical choice points in the developmental process or continuously from early childhood, situational and social-structural variables may produce effects influencing adult patterns—for instance, the feminizing effects of older sisters on younger brothers, situationally determined isolation from peers of the same sex in childhood and adolescence, or isolation from peers of the opposite sex in adolescence.

From the limited evidence currently available, it is clear that the diverse forms of adult homosexuality are produced by many combinations of variables, including biological, cultural, psychodynamic, structural, and situational. No single class of determinants, whether psychodynamic, cultural, or biological, accounts for all or even one of these diverse forms. The relative importance of each kind of determinant appears to vary greatly from one individual to another. It should be noted, however, that the classification of types of homosexuality with respect to patterns of determinants and characteristic adult features is an important problem for research. It is also clear that many developmental models are required to account for the diversity of developmental sequences leading to confirmed patterns of adult homosexuality. The continued search for determinants may be more

productive if pursued in the perspective of development over time, rather than in the traditional perspective of origins or causes.

### Psychodynamics of adult homosexuality

Psychoanalytic theories assume that homosexuality is a symbolic expression of unconscious psychodynamic mechanisms and that in any given case these mechanisms and symbolizations are complex and numerous. Thus, according to Freud (1905), male homosexuality may be a narcissistic search for a love object symbolizing the self; an avoidance and derogation of females induced by unconscious castration anxiety and fear of them, coupled with primary narcissism focused on the male genitals; and an unconsciously incestuous and therefore forbidden attraction to women associated with unconscious castration anxiety and fear of punishment by males. Stronger identification with the mother is symbolically expressed in "feminine" sexual submission to males; that with the father, in "masculine" domination of males. Freud postulated similar complex symbolic expressions of unconscious psychodynamics for female homosexuality; the primary difference between male and female homosexuality, he thought, related to the nature of castration anxiety. However, there is a paucity of theoretical assumptions that differentiate male and female homosexuality with respect to personality dynamics and its correlates (see Romm 1965). Ambivalence, chronic anxiety, intense hostility toward the partner, and longing for love characterize female homosexual relationships, according to Wilbur (1965). Thompson (1947) considered homosexuality in both sexes as a symptom of diverse character problems covertly expressed in homosexual relations (among these problems were fear of the opposite sex, need to defy authority, fear of adult responsibility, and destructiveness of self or others). These theories involve complex patterns of variables that are difficult to state as clear hypotheses. Consequently, the design of an appropriate methodology for testing them presents problems. Research studies have therefore focused on selected aspects of the theories or variables for which clinical impression or theoretical rationale provides justification.

**Masculinity and femininity.** A major focus of research studies on male homosexuality is the complex issue of psychological masculinity-femininity and its relation to gender identification. Terman and Miles (1936), using masculinity-femininity test scores and interview data, compared "passive" male homosexuals (defined by "female" roles in sexual acts) with "actives" (de-

finer by "male" roles) and then compared both of these with (presumably) selected groups of heterosexual men and women. The femininity scores of the passives were higher than those of any other male group tested. The masculinity scores of the actives were higher than those of the passives and of a group of regular-army men. These results suggested that individuals in both homosexual groups represented deviations in masculine and feminine identifications, interests, activities, and feelings. Interview data on the passives supported the masculinity-femininity test results. Similar results were obtained on a small sample of active female homosexuals.

In subsequent studies of masculinity-femininity, data on sexual practices and preferences are rarely reported, but the evidence from research on other dimensions of male homosexuality indicates that samples of homosexuals usually include many individuals whose preferences and practices are highly variable, as well as those representing the two extremes of active and passive (Society of Medical Psychoanalysts 1962; Hooker 1965*b*, Schofield 1960). The distribution of the scores of homosexuals and control groups of heterosexuals on the masculinity-femininity scale of the Minnesota Multiphasic Personality Inventory (MMPI) indicates that homosexuals are significantly more "feminine" in their responses than heterosexuals. Thus, Doidge and Holtzman (1960, p. 11) found that a group of homosexual men in the Air Force who had been investigated for homosexual offenses scored significantly higher (that is, were more "feminine") than three control groups of predominantly or exclusively heterosexual men. Braaten and Darling (1965, p. 298) found that, while overt homosexual males (including exclusives and bisexuals) and covert homosexuals who were patients in a college clinic did not differ significantly on masculinity-femininity scores, as a total group (overts plus coverts) they scored significantly higher than a control group of equally disturbed, nonhomosexual patients. Although a group of homosexual males who were not in treatment and were apparently functioning effectively in the community scored significantly higher than a control group of heterosexual males on the masculinity-femininity scale of the MMPI and the femininity scale of the California Personality Inventory (CPI), significant differences were not found in scores on various projective measures designed to assess unconscious gender identification (unpublished research by the author). Feminine identification and confused or unstable gender identification in male homosexuals have

also been assessed by the use of content indices in the Rorschach Test and the Thematic Apperception Test (TAT). The interstudy reliability of these indices in differentiating homosexual and heterosexual groups is low (Hooker 1965*a*; Lindzey 1965). Chang and Block (1960), using a list of adjectives, derived identification scores from descriptions by male homosexual and heterosexual research subjects of the ideal self, the mother, the father, and their actual selves. The results supported the hypothesis that homosexual males were more strongly identified with the mother and did not identify with the father.

Conclusions from these findings must be drawn with caution. Psychological masculinity and femininity are not unitary dimensions of personality but composites of different clusters of interests, attitudes, and feelings. The test measures are also multivariate in character. Thus, high "femininity" scores may indicate ego sensitivity and denial of interest in culturally masculine occupations (Braaten & Darling 1965). Research findings currently available do not provide even roughly sketched outlines of the complex patterns of psychological masculinity-femininity and gender identification in male or female homosexuals. If current measures of these variables are to remain in use, the multivariate character of what is being measured must be taken into account. Also, new and more appropriate methods must be devised for assessing different clusters or profiles of the conscious, unconscious, cultural, and biological components of masculinity, femininity, and gender identification. The selection of samples of research subjects must make allowance for the broad range and diversity of masculine and feminine patterns and the variable combinations of these.

**Other personality dimensions.** The evidence supporting assumptions related to other psychodynamics or personality correlates is equally inconclusive. Bieber and his co-workers (Society of Medical Psychoanalysts 1962) concluded that their findings provide convincing support for the assumption that homosexuality is a specific form of sexual psychopathology: fear of the opposite sex or of heterosexual expression. But none of the evidence, such as fear of injury to the genitals, fear and aversion to female genitalia, or anxiety associated with heterosexual behavior, was specific to the homosexual group. The evidence cited for the conclusion that other psychopathologic processes in personality are secondary but invariably occur in homosexuals is subject to the same limitations. Moreover, the research subjects were patients in psychoanalytic treatment, so that the relation be-

tween psychopathology and homosexuality was confounded. Braaten and Darling (1965) found no evidence to support assumptions that homosexuals, as rated by psychiatric interviewers, were more psychopathic, paranoid, or schizoid than a control group of heterosexuals and found no differences in psychopathology as measured by the MMPI. Psychiatric ratings on narcissism and masochism were higher for homosexuals but not specific to them. The significantly higher scores of homosexuals on all clinical scales of the MMPI were interpreted by Doidge and Holtzman (1960) as evidence that homosexuality is a symptom of severe personality disturbance. In a number of studies of male homosexuals who were not in treatment or in disciplinary settings, the results obtained by the use of the MMPI, TAT, Rorschach, and other psychological measures did not justify the conclusion that homosexuality is necessarily and invariably a concomitant or symptom of psychopathology. In many individuals no evidence of psychopathology was found (Hooker 1957; 1965a). Nevertheless, the assumption that a modal pattern of personality structure and psychodynamics characterizes male homosexuals is explicitly stated or is implicit in the methodology used in many research studies. Having been unable to establish any differences between a group of homosexual males and a control group of heterosexuals, either in degree of self-acceptance or in ideal-self descriptions, Chang and Block commented that since "homosexuals and normals are quite obviously rather different sorts of people," their data must be regarded as questionable (1960, p. 309). Nevertheless, the only obvious difference between homosexuals and heterosexuals is in psychosexual object choice. All experienced clinicians and research workers report that the personality differences among individual homosexuals are far more apparent than the similarities. Investigators who include the data on individual differences in their studies have found a great diversity of personality patterns. A singular exception is the finding of Cattell and Morony (1962) that low ego strength, high extroversion, low superego, and a radical social outlook characterize the personality profiles of male homosexuals. They conclude that it is legitimate to speak of *the* homosexual-personality profile.

The inconclusiveness of research on homosexuality is a function of many variables, including differences in investigators, in samples of research subjects and situational settings, in methodology, and in concepts of homosexuality. Lindzey (1965) has demonstrated the significant influence of many of these variables in a study designed to

cross-validate objective indices of homosexuality in the TAT and to test the predictive efficiency of clinical methods of diagnosing homosexuality compared with actuarial ones. The limitations of psychological tests in the diagnosis of homosexuality have been documented in many studies. Inferences from these measures and generalizations about the personality characteristics of homosexuals must be made with caution and within the limits set by the characteristics of the research sample, the setting, and the methodology.

With few exceptions, studies of the personalities of homosexuals have been stated in terms of dichotomous attributes—psychopathology versus normality, specific sexual psychopathology versus pervasive personality disorder, feminine versus confused identification, feminine versus masculine identification, and other pairs of mutually exclusive variables. Thus, in effect, homosexuality has been treated as a clinical entity. But contemporary personality theories are richly suggestive of dimensions or subsystems of personality that are potentially relevant to psychosexual patterns, and until now, these theories have scarcely been tapped as sources of hypotheses. Some of the effects of a changing climate of public attitudes toward homosexuality and of an increasing freedom to conduct scientific studies of human sexuality in all of its complex psychological, social, and biological aspects are manifested in the small but growing number of behavioral scientists whose interests and competence in personality research are focused on homosexuality. With the cooperation of homosexuals in the "homophile" and larger communities, it is no longer necessary to depend on subjects in clinic or prison settings. With the use of more rigorous criteria in selecting homogeneous samples of subjects and of more appropriate research designs, including cluster and profile analyses, it may be possible to differentiate personality patterns among homosexuals. Also, progress may be achieved in resolving the long-debated issue as to whether some homosexuals differ from their heterosexual counterparts only in sexual object choice or are invariably different in some personality dimensions.

### Role differentiation and typology

The perspectives of the two-sexed heterosexual society have so dominated the study of homosexuality that typologies of homosexual and related roles have been developed only to a very limited extent. Thus, Ferenczi (1914) distinguished between male inverts who have pervasive feminine identifications and assume a passive sexual role

and males who assume an active sexual role and are apparently masculine in every respect except sexual object choice. Many theoreticians and empirical investigators (see, for instance, Terman & Miles 1936), while emphasizing the active-passive dichotomy in sex roles and the corresponding masculine-feminine dichotomy in gender identifications, have noted that the patterns of many male homosexuals represent variable combinations and intermediate grades. Recent studies (Schofield 1960, Society of Medical Psychoanalysts 1962, Hooker 1965b) have shown that the terms "activity" and "passivity" may be useful in referring to psychological states but are inaccurate and misleading when applied to sex roles and should therefore be discarded. The terms "insertee" and "insertor" (Society of Medical Psychoanalysts 1962) are more accurate and operationally useful equivalents. Studies of the sex-role preferences and practices of male homosexuals indicate that a large proportion of them habitually perform either role, according to their own or their partners' momentary preference. For the majority, consciousness of male identity and of masculinity or femininity appears to show no clear relation to sex roles. Sustained dyadic relations and the shared perspective of male homosexual subcultures appear to increase the flexibility of social-sexual roles and to create the social conditions for the emergence of new solutions to the problems of role differentiation in a one-sex world (Hooker 1965b).

Studies of male homosexuality in correctional institutions (Huffman 1960; Sykes 1958) suggest that homosexual social-sexual roles are clearly defined by inmate codes. According to these codes, the masculinity of the individual who assumes the insertor role in a homosexual act is not diminished and may even be increased. Within the institution, the role carries no implication that the individual is homosexual. Emotional involvement with a partner appears to be rare. Gratification of needs for power, status, and sexual release is presumably legitimate motivation for assuming the role. Individuals who assume insertee roles occupy social positions of inferior status to which stereotyped attitudes of femininity and homosexuality are ascribed. These traditions apply only to institutions in which known homosexuals are not segregated from the rest of the prison population.

As noted above, the literature of female homosexuality is fragmentary in comparison with that of male homosexuality. Studies of role differentiation have been conducted largely in correctional settings for adolescent girls or prisons for adult

women. In prisons for women a male-female dichotomy in social-sexual roles develops and is sustained with little flexibility or variation (Ward & Kassebaum 1965). The masculine, or "butch," role is characterized by emulation of the male in appearance, mannerism, and aggressiveness in social interaction as well as in sexual relations. The feminine role is identical in the prison and in the larger society, except for the sexual partner. The woman who assumes the masculine role becomes emotionally involved with her feminine role partner and defines herself as homosexual more frequently, and receives sexual gratification less frequently, than her counterpart in the male prison. Whether the clear-cut male-female role differentiation in prison settings is also characteristic of female homosexual patterns in the larger community is unknown. Despite the differences, the similarities of homosexual role differentiation in men's and women's prisons are striking. It appears that individuals in both settings who assume opposite-sex roles are more likely to have been overt homosexuals before entering prison and to continue homosexuality on being released. In studies of correctional settings for adolescent girls, it has been found that the roles assumed in the course of homosexual relationships represent variations of all family roles.

The empirical data obtained in the restricted environments of correctional institutions for men and women support a dichotomous typology of homosexual roles in which the male and female social-sexual roles in the larger community are reflected. However, male homosexual role patterns in other cultural settings appear to show extensive variations for which a taxonomy, or system of classification, is urgently needed. Studies of female homosexual role patterns in nonprison settings—several were in progress in 1964—can provide the necessary data for a comparison of variability within and between the sexes. The development of taxonomies of male and female homosexual patterns is a theoretical problem of paramount importance. To be meaningful, such taxonomies must include variations in many dimensions of personality, in sexual and social behavior, and in the social settings or subcultures in which many homosexuals participate.

**Demographic and cultural variation.** In undertaking empirical research on the incidence or demographic distribution of homosexuality in urban industrialized societies, investigators are confronted with two major questions: 1. What or what is to be counted as homosexual? and 2. How can representative samples be obtained in

of the sexual status of individuals whose behavior is socially, morally, and legally stigmatized." In view of the magnitude of these problems, it is not surprising that few have even attempted to solve them. The most systematic research studies of the incidence and social correlates of homosexuality are those of Kinsey and his associates (1948, 1953), who rejected the counting of homosexuals as an inappropriate and impossible task. Accumulative estimates of incidence were based on the number of individuals brought to orgasm by physical contact with others of the same sex during specified periods. They attempted to collect interview data from samples of equal size, varying in demographic characteristics. The samples (6,300 white males, 5,940 white females) were neither representative of the total population nor random around them.

The Kinsey studies the estimated incidence was reduced by the following: (1) 4 per cent had at least one overt homosexual experience between the ages of adolescence and old age, (2) 10 per cent were predominantly homosexual for at least three years between the ages of 16 and 75, (3) 4 per cent were solely homosexual after the onset of adolescence. For white females, the estimated incidence was much lower: (1) 13 per cent had at least one overt homosexual experience between adolescence and old age, (2) 28 per cent had covert or overt experience, (3) a half to a third as many females were primarily or exclusively homosexual in any age period.

The major findings on the social correlates of homosexual activity for males were that the highest incidence occurred among unskilled and semiskilled workers and the lower white-collar class, among those with high school education and of other religious, and among the less devout or inactive church members. The lowest incidence occurred among the professional and upper white-collar classes and in the college-educated group. However, the incidence among skilled workers was closer to that among the professional and upper white-collar classes than to that among the lower occupational groups. Those with grade school education showed a level of homosexual activity intermediate between that of high school and that of college-educated groups. Homosexual activity in females increased with education so that the incidence was highest among those with college or postgraduate education. For males, the opposite was true. For both males and females the highest incidence occurred among the less devout or least active in church affiliation.

Although the assumptions, methods, and conclu-

sions of these studies are highly controversial, their findings are most frequently used as evidence for a high incidence of homosexuality in the United States. They are also based on the basis of rather limited demographic evidence to support the assumption that cultural differences between social groups determine the unequal distribution of homosexual activity in different segments of society.

This assumption also appears to be supported by Schofield's study in England, 1965. A group of 127 men who identified themselves as homosexuals to the investigator and were also rated by him as predominantly or exclusively so were interviewed concerning their backgrounds and current social and sexual patterns. The largest proportion of men were in lower occupational levels and the smallest in the professional group, a distribution of men among occupational levels that is similar to the total population. However, the number of men in nonmanual and artistic occupations and in the professions exceeded chance expectations and those employed in a technical capacity and manual workers were underrepresented. In educational level attained, the sample was similar to the total population in that the largest number had the statutory minimum of education. However, the number of those with extensive education and high social status was higher than would be expected in a random sample of the total male population. The majority of these men lived in London to which a large proportion of them had migrated from other urban centers. Active church affiliation was only slightly lower than that of the general population. In a continuation of this study, fifty men were selected who had been neither convicted of homosexual offenses nor involved in therapy of any kind (Schofield 1965). They were compared with an equal number of men in three groups: homosexuals in prison, homosexuals in therapy, and pedophiles convicted of offenses against males. On Kinsey ratings, the prison group was predominantly or exclusively homosexual, the patient group included a small number who were equally homosexual and heterosexual, or predominantly heterosexual, a quarter of the convicted homosexuals and 60 per cent of the pedophiles were either equally homosexual and heterosexual or predominantly heterosexual. In educational achievement, occupational status, earned income, social class and upward social mobility, the men who were neither in prison nor in therapy ranked highest and the prison groups lowest. The four groups were differentiated not only in their demographic characteristics but also in their patterns of social and

sexual relationships. Thus, the men who had not sought treatment or been arrested were better integrated into the larger community both at work and in their leisure time. They also had larger circles of homosexual friends and more long-standing relationships with other men. Only in this group were there substantial numbers of men who maintained a household with another homosexual. They were far less promiscuous than the patient or prison homosexual groups, although the frequency of sexual experience was equally high.

It is apparent that comparison of the findings in this British study with those in the Kinsey report has limited meaning. However, some similarities and differences are of interest. In both studies, homosexuals were found in all social classes, educational levels, and occupations. A larger proportion of homosexuals (or of homosexual activity) in all studies took place in urban settings and in lower occupational levels and social classes. In educational achievement, however, the proportion was greater in the middle level (high school) in America and in the lower level (secondary modern school) in England. That in both countries the distributions were skewed toward the lower end of the occupational and social class range may well be accounted for by the fact that individuals in higher levels would not volunteer to be interviewed. The same limitation is relevant to the Kinsey finding that the incidence of homosexual activity is lowest among the most devout religious groups. Moreover, in the English studies the incidence of active religious affiliation did not appear to be significantly lower among homosexual males.

In short, whether homosexuals or homosexual activities among males or females are more heavily concentrated in different social strata remains an open question. Whether the social patterns or incidence of those who *define* themselves as homosexual are different in varied social levels is of equal or possibly even greater importance.

**Ethnographic accounts.** In a survey of studies of sexual behavior in 190 societies, Ford and Beach (1951) found that ethnographic accounts of homosexual activities were available for 76. In 49 of these some forms were condoned, regarded as normal or socially acceptable, and even encouraged for at least some classes of individuals. In some cultures, such as those of the Siberian Chukchee and the Aleutian Koniaga, an institutionalized role of berdache, or shaman, is provided for adult male homosexuals. These men adopt feminine dress, activities, mannerisms, become "wives" of other men, and assume the "female" role in anal inter-

course. Their social status may be high. Male homosexuality in some societies, for instance among the Keraki and Kiwai of New Guinea, is an institutionalized feature of puberty rites. Thus, all males must engage in homosexual practices, either as initiates in the insertee role in anal intercourse or as married or unmarried males who perform the inserter role. Such practices are believed to be essential for male growth and strength. It has also been reported that all men and boys among the Siwans of northeast Africa engage in homosexual practices; married and unmarried males have homosexual and heterosexual liaisons. In 28 of these societies, adult homosexuality was reported to be rare, absent, or only practiced in secret. In all societies (except that of the Sirione in Bolivia) in which homosexuality was said to be rare, specific social pressures were directed against it. Condemnation and penalties ranged from ridicule to threat of death. The unreliability of the estimates of incidence in these societies was apparent. Information concerning female homosexuality was reported for only 17 societies. It appeared highly probable that females were less likely than males to engage in homosexual practices.

In view of the small number of societies for which data are currently available and the questionable reliability and meaning of the data in the many studies that report sexual behavior while ignoring its context of culture patterns and social structures, it is apparent that descriptive or explanatory generalizations concerning demographic and cultural variations in homosexuality are precariously based. Whether a majority of societies consider some form of homosexuality normal and socially acceptable is an important issue for continued cross-cultural research. Clearly, some societies not only consider adolescent or childhood homosexuality normal (some evidence suggests an increasing trend in this direction in the United States) but also regard homosexual relations between adult and adolescent males as important, normal, and socially approved alternatives to heterosexual intercourse (Davenport 1965).

**Subcultures and social organizations.** Homosexual communities and subcultures in modern urban centers are collective reactions to legal pressures and social stigma. Whether they are largely created by societal reactions to this form of sexual expression (Becker 1963) or, on the contrary, would develop under any sociolegal conditions is debatable (Schur 1965, p. 86). A central thesis in contemporary theories (Lemert 1951; Becker 1963; Goffman 1963) is that deviant as well as conform-

ing behavior is learned in interaction with others and that it cannot be understood without reference to the societal reactions it invokes. Male homosexual collectivities develop on a sizable scale only in modern industrialized societies, which define this form of sexual expression as criminal, pathological, or immoral. In adjusting to this stigmatized status, a large number of homosexuals in social interaction with others who share similar inclinations make it the basis of their social identity and way of life. A larger majority cope with the problems of homosexuality in other ways, whether or not they enter some sector of a homosexual community.

Homosexual communities in large cities are made up of constantly changing aggregates of persons who are loosely linked by friendship and sexual interests in an extended and overlapping series of networks. Some network clusters form tightly knit cliques of friends and homosexually "married" pairs, while in others, informal groups or social organizations develop. The structure of the communication, friendship, and sexual network among members of the community is complex. Community gathering places are centers from which information is transmitted concerning social occasions for homosexuals and the attitudes and organized activities of law-enforcement agencies concerning homosexuals. In some sectors of these networks, bars, taverns, or private clubs are informally institutionalized as homosexual territory, although under surveillance of the police, who sometimes exact tribute for their connivance. These settings provide opportunities for the initiation of sexual contact and for an in-group social life. Some are primarily market places for making sexual contacts, while others are predominantly centers of social activity, although arrangements for sexual activity may occur. A standardized and essential feature of interaction in bars, baths, streets, and parks is the expectation that sex can be had without obligation or commitment. Sexuality is separated from affectional and social life and is characterized by promiscuity, instrumentality, and anonymity. In other sectors of the homosexual community, sexuality is integrated in the affectional, personal, and social patterns of individuals who establish relatively stable and long-lasting relationships.

Many subcultures develop in large homosexual communities, with a distinctive vernacular, distinctive modes of speech and dress, distinctive values and norms regulating sexual and other forms of conduct, and distinctive patterns of interaction

with homosexuals and nonhomosexuals. Some individuals may be totally immersed in a homosexual subculture of the community. A wide variety of occupations is created by the demand for services to homosexuals. Male prostitutes, many of whom are homosexuals, constitute one occupation (Reiss 1961; Schur 1965). Entrepreneurs who are homosexual may develop an occupation in arranging social entertainment and large social gatherings for members of a particular homosexual group. Thus, at work and in leisure time, in personal and social life, contact with the larger society may be infrequent. For the majority, however, behavioral, temporal, and spatial separation of the homosexual and heterosexual worlds is required to manage the strategies of passing as heterosexuals at work and in social contact with heterosexuals. In fact, there are many different methods, some of them quite complex, both of participating in the homosexual community without leaving the larger society and of ignoring the larger society altogether. Related to these patterns of integration and separation are the different social levels of homosexual groups.

Female homosexual, or lesbian, communities apparently develop on a smaller scale, with informal groups, cliques, and special gathering places. But a formal organization of lesbians and an official publication with national circulation indicate that the collective aspects of female homosexuality have some importance. No empirical studies of these aspects are currently available. Although homophile organizations, whether male or female, constitute and represent a very small minority of the total homosexual population, they achieve social significance by the role they assume in openly protesting the status assigned to homosexuals by the larger society.

Empirical studies of, and theoretical inquiry into, homosexual subcultures are very limited (Leznoff & Westley 1956; Hooker 1965a; 1965b). They suggest that commitment to a homosexual identity and career and the stability of that commitment and the career pattern that follows may be determined by entry into the homosexual community and by the ensuing identity transformation and socialization processes. However, the relation between personality and homosexual subculture variables in determining the commitment to, and patterns of, adult homosexuality is complex. For many the stability of the commitment appears to be a function of the interaction of both sets of variables. Probably a majority of those who are committed to an exclusive homosexual pattern have defined themselves as homosexual before they

enter the community. In major urban centers, however, it appears unlikely that adult homosexuals are ignorant of, or indifferent to, the community.

## SHAMANISM

See RELIGIOUS SPECIALISTS.

## SHANG YANG

Shang Yang (also known as Wei Yang or Kung-sun Yang), who died in 338 B.C., was a Chinese political administrator who left his native state of Wei to enter the service of Duke Hsiao of the state of Ch'in. At the time, the feudal hierarchy dominated by the Chou dynasty had degenerated into a struggle for power among feudal principalities, and Duke Hsiao's consuming concern was to build up Ch'in strength and become a leader among the contending states.

Although it is questionable whether Shang Yang himself wrote *The Book of Lord Shang*, which has been ascribed to him, the conception of a state that is presented in this work is very likely similar to his, and it was therefore surely influential in the reforms he instituted to fulfill Duke Hsiao's ambition. "The central idea of the political theory expounded in *The Book of Lord Shang* is the necessity for creating a strong government; the strength of a government is relative to the weakness of the people and is insured by a strict rule of law" (Duyvendak 1934, p. 16).

Power, for Shang Yang, consisted of a large army and a full granary. He was convinced that the maximum strength of the state could be obtained only through state-wide mobilization, and this in turn required a system of effective laws enforced by severe punishment. He succeeded in instituting laws that applied uniformly throughout the state and equally to all classes of people. The laws were codified and made public, and a judiciary was set up that was independent of the administrative offices of the government. In addition, Shang Yang proposed and implemented a new system of land division, based on private ownership, together with a tithing system of taxation. In accordance with the principle of centralized govern-

ment, military service was owed only to the state, and all private military action was prohibited.

Shang Yang's administrative system was a success. In ten years the state was reputedly rid of lawlessness; it was highly centralized and bureaucratized; and it pursued a victorious policy of foreign war. When the Ch'in state succeeded in subduing all its rivals and reunifying the empire in 221 B.C., the programs initiated by Shang Yang were introduced and extended throughout the empire.

Shang Yang did not long survive the death of Duke Hsiao in 338 B.C. His severe and egalitarian laws had aroused much resentment on the part of the nobility and the privileged classes, and they took the first opportunity to turn against him. His attempts first at flight and then at armed resistance failed, and he was put to death.

*The Book of Lord Shang* remains a valuable record of the social and political philosophy of the ancient Chinese school of law in general and of Shang Yang in particular. The "school of law" stressed the importance of government by law, as opposed to the Confucian ideal of government by "moral virtue." Traditional China, dominated by Confucianism, therefore regarded Shang Yang and the other members of the legalist school with suspicion and abhorrence and condemned Shang Yang for having no moral sense or human feeling. Modern China has re-evaluated him more favorably. The ideas and institutions associated with his name now appear to contain a number of elements considered necessary to the modern administration of law and government. In Shang Yang's approach to politics, however, an informed public played no role, nor were there any safeguards against a ruler who wished to substitute his own whims for the welfare of the state.

## SHERRINGTON, C. S.

Sir Charles Scott Sherrington (1857-1952) made an overwhelming contribution to the foundations of modern neurophysiology through his ex-

periments and theories on the functioning of the spinal reflexes. Sherrington's importance to the behavioral scientist lies in the fact that he used mainly the methods of behavioral science to pursue his investigations. He studied the behavior of animals after the influence of higher neural centers had been removed surgically by spinal transection. From such behavior he formulated hypotheses about the nature of the nervous system, which he tested by further experiment.

Sherrington was born in London, the son of a country doctor. Although his curriculum at school did not include science, he later enrolled as a medical student at St. Thomas's Hospital in London. Before he completed his clinical studies there in 1885 he worked in the physiology school at Cambridge University and he also spent almost a year with Friedrich Goltz and Carl Anton Ewald in Strasbourg. It was in Goltz's laboratory that he saw the reactions of a dog with a high spinal transection. The investigation of such phenomena was to form his major scientific interest until 1935, the date of his retirement from the Waynflete professorship of physiology at Oxford. Although something was known of reflex action in a general way, Sherrington's thorough investigations transformed the study of reflex action into a tool for the understanding of nervous activity.

His book *The Integrative Action of the Nervous System* (1906) summarizes his most important contributions. The problem that Sherrington posed himself was how the truncated nervous system of the spinal animal produces motor reactions that are coordinated both in space and in time when stimuli are applied. He saw that stimulation of motor pathways alone leads to contortions rather than to actions and that the properties possessed by nerve trunks alone are not sufficient to endow the nervous system with the means of achieving the behavior that he observed. To account for the difference in reaction to different stimuli Sherrington had recourse to the notion of an adequate stimulus, or the idea that the function of a receptor is to make available a particular reflex only to specific physical stimuli. Furthermore, Sherrington was struck by the presence of an after-discharge (the tendency for a reaction to persist after the stimulus has been withdrawn), by differences in latency of reaction when stimuli of differing strength are applied, and by the irreversibility of conduction in the reflex arc. To explain these and other discrepancies between the action of nerve trunks and the nature of the connection between stimulus and response, Sherrington postulated the functions of the synapse, the name of which he

coined. This synaptic hypothesis, based almost entirely on behavioral observations, has now been strikingly verified by advances in experimental technique. On the synaptic hypothesis, messages travel from one nerve cell to another across a small gap between the two cells. Thus there is a functional connection between the two cells as distinct from a physical fusion of their membranes. Transmission across this gap is different in kind from transmission along the processes of the nerve cell itself. (It is now known that in the vertebrate nervous system such transmission across the synapse generally occurs by means of diffusion across the gap between the nerve cells—the synaptic cleft—of small amounts of chemical substances, such as acetylcholine.) He used this hypothesis further to account for interactions between reflexes, and he also introduced the notion of the final common path, thus narrowing down the locus at which one reflex inhibits another. He provided a detailed physiological basis for the mechanism of chain reflex, a notion propounded both by Exner and by Jacques Loeb, which is of great importance to behaviorism.

It should be stressed that Sherrington, in his more than three hundred publications, made contributions to many fields other than neurophysiology, among them the physiology of blood, the psychology of contrast and flicker, and the functional localization of the motor cortex. He was also one of the early scientists to work on the neural basis of the emotions. His discussion of the James-Lange theory in the seventh chapter of *The Integrative Action of the Nervous System* is still one of the best in the literature. The excellence of his work won wide recognition, and in 1932 he was awarded the Nobel prize for medicine.

Although Sherrington probably contributed more than anyone else to the purely mechanistic understanding of reflexes, he also found it useful to consider them in terms of their purpose, or biological utility. And he was not averse to devoting thought to the more philosophical aspects of the functioning of the nervous system. In his extensive writings on the subject he argued for a Cartesian dualism of body and mind, a position in which Sir John Carew Eccles, another distinguished neurophysiologist, has followed his teacher.

In spite of their profound influence on physiology, the details of Sherrington's observations and thoughts have little affected the mainstream of behavioral science. However, the general impact of his work, whether rightly or wrongly, contributed to the vogue for analysis in terms of the reflex or of stimulus-response psychology.

### SIDGWICK, HENRY

Henry Sidgwick (1838–1900), English economist, does not have an obvious place in the standard histories of economic or social thought. His name is not associated with any particular theory or policy, and much of his influence was exerted through his teaching and his participation in the affairs of Cambridge University.

Sidgwick was born at Skipton in Yorkshire, where his father was an Anglican clergyman and headmaster of the local grammar school. From his earliest years it was clear that Sidgwick was destined for academic success. After attending Rugby, he went to Cambridge and achieved distinction there, both in classics and mathematics. In 1859 he was elected to a fellowship at Trinity College; he remained at Cambridge for the rest of his life.

At the beginning of his academic career Sidgwick taught classics, but he was soon drawn into the field of social science and in 1867 exchanged his lectureship in classics for a lectureship in moral sciences (what would now be called social sciences). Much of his intellectual effort as a teacher at Cambridge was directed toward improving the curriculum: he was influential in raising the status of the social sciences, and he helped pave the way for the economics tripos. Thus, he may be regarded as one of the pioneers who facilitated the emergence of the "Cambridge school" of economics. He also furthered the cause of univer-

sity education for women (his wife became principal of Newnham College in 1892), and he played a part in the movement for greater religious toleration at the university.

His writings ranged over a number of fields: in addition to his early classical studies, he wrote on politics, philosophy, and economics and, more remote from his central concerns, attempted to make research on psychic phenomena (then a particular vogue in England) scientifically respectable. All who came in contact with Sidgwick seem to have agreed about his intellectual and moral stature; Marshall spoke of him as his "spiritual father and mother," and John Neville Keynes described him as the most intellectually gifted man he had ever met.

Sidgwick's written contributions to economics are to be found mainly in his *Principles of Political Economy* (1883). This work is a useful benchmark by which to judge the state of the discipline in the period between J. S. Mill's *Principles* (1848) and the first edition of Marshall's *Principles* (1890). The text is primarily a re-exposition of Mill, with traces of the emergent marginalism of Jevons and Marshall. Like Marshall, Sidgwick had a strong desire to emphasize continuity in economic thinking, rather than his own originality. As he put it, "The special aim . . . is to eliminate needless polemics by a guarded restatement of traditional doctrines, with due recognition of the advances made in economic theory by recent writers" ([1883] 1901, p. ix). The book contains some corrections and clarifications of Mill's analysis (for example, the distinction between movements along a demand schedule and shifts from one demand schedule to another, which is so blurred in Mill, is clearly made and explained by Sidgwick), and the influence of Marshall is obvious.

The most important sections in Sidgwick's *Principles* are those dealing with methodology and the analysis of government interference. Sidgwick restated the methodological position, first enunciated within the context of economics by Senior and Mill, whereby the "science" and the "art" of political economy are to be logically differentiated: "The first gives information as to what happens, without pronouncing whether it is good or bad; the second judges that what happens or would happen under certain conditions is the best thing that could happen" (*ibid.*, p. 36). However, Sidgwick (ever a moderate) refused to adopt the extreme position of Cairnes, and later of Robbins, according to which the economist qua economist has no special qualifications in the normative area of his studies.

The core of Sidgwick's major contribution is

contained in his discussion of the art of political economy (book 3). He was at pains to dissociate economic science from the political doctrines of laissez-faire and suggested various conditions under which state interference in the productive process may become desirable: one important condition is the divergence of private and social benefits. Here Sidgwick's analysis constitutes the prototype of the Marshall-Pigou approach. However, he did not present a general a priori case for government interference whenever this divergence obtains—each situation has to be considered on its own. He stated the case for interference with the distribution of income—necessitated by an unregulated economic system—with much more generality, except for reservations about the possible effects of interference on production. He argued for much greater equality of income, to be achieved by deliberate government fiscal policy, basing his argument on the "general acceptance" of two propositions of Bentham's, which may be summarized as follows: utility increases as wealth increases, but at a decreasing rate. Sidgwick did not make clear the methodological status of these propositions; we are not told whether they are judgments or testable (and tested) hypotheses.

Sidgwick's influence on social thought and policy is difficult to assess. Although he expressed grave doubts about the feasibility of a total socialist solution, his rejection of any general theoretical reasons for nonintervention and his emphasis on the need to look at every case individually place him squarely in the English Fabian tradition.

BERNARD CORRY

## SIEGFRIED, ANDRÉ

André Siegfried (1875-1959), French geographer and political scientist, gained world-wide recognition through his development of a new approach to the study of political parties known as *géographie de l'opinion politique*, or political ecology; through his studies of French political regimes; and through his more general studies of the United States and other countries.

Siegfried was born in Le Havre, the son of a wealthy Calvinist Alsatian merchant who served as mayor of Le Havre from 1878 to 1886 and as a member of the Chamber of Deputies from 1885 to 1922. His mother was the daughter of a pastor in the Reformed Church and came from the *département* of Ardèche, which Siegfried later chose as the subject of one of his studies in political ecology. His parents liked to entertain, and Siegfried had the opportunity, first in Le Havre and later in Paris, of meeting in his home the political elite of the Third Republic. As a young man, he accompanied his father, who was a passionate traveler and keen observer, on some of his journeys abroad, an experience which was important for his own later efforts to describe and compare foreign countries. His father, as mayor and as a deputy, initiated many social reforms, thereby setting an example for Siegfried's activities in this field.

Siegfried's interest in politics led him to run for the National Assembly. He was unsuccessful and decided instead to focus his political interest on the compilation of "a psychological and political geography of France." The first volume, *Tableau politique de la France de l'ouest*, appeared in 1913, but the series was interrupted by World War I. Siegfried did not return to his geographies of electoral behavior until after World War II. He then published *Géographie électorale de l'Ardèche sous la III<sup>e</sup> République* (1949a) but after that left further studies to his disciples, publishing only his basic ideas on this kind of inquiry.

Siegfried served as a professor at the *École Libre des Sciences Politiques* and from 1933 to 1946 held a chair in economic and political geography at the Collège de France. Apart from his writings his main influence came through his two courses at the

Collège de France, one on the geography of political parties in France and the other on the economic and political geography of the world. In 1942, during the German occupation, he became director of the Musée Social, an institute that his father had founded for the preparation of social legislation. He had had a large part in the establishment of the Université Populaire de Belleville, one of the earliest institutions for adult education of workingmen. He was also active as a journalist, and through his articles in *Figaro* during World War II "he became one of the most effective leaders of public opinion" (Jean Schlumberger in *André Siegfried 1875-1959* 1961). After World War II he became director of the Institut d'Études Politiques in Paris. He was elected to the Académie Française in 1944, the first geographer to be so honored.

Before and after World War I, Siegfried traveled in Great Britain, the United States, Canada, Australia, and New Zealand. "It was an opportunity," he wrote later, "to observe democracy as practiced with the Anglo-Saxon spirit and methods. Instead of the aggressive and somewhat negative individualism of the Latin civilization, I saw political societies based on social cooperation. At bottom it seemed to be a contrast between the Catholic and Protestant state of mind, religion leading to extraordinarily different consequences" (1930, p. vi). This experience reinforced his interest in the political institutions of his own country.

Siegfried's studies of foreign countries are comprehensive monographs in the tradition of Tocqueville. Each of them has a central theme: the books on New Zealand (1904) and Canada (1906) are concerned with the formation of new nations and the books on Britain (1931) and the United States (1927) with their changed positions in the world. The books are masterful syntheses of the economic, political, and cultural aspects of large complex societies, always presented with a historical perspective and a geographical foundation. He gave his major attention to class structure, to religious orientations and cleavages, and to race. Since he had more than once visited some of the countries he wrote about, he was able to observe important social changes directly. His wide range of knowledge in economics, political science, and history and his acquaintance with both the Latin and Anglo-Saxon worlds enabled him to make use of cross-cultural comparisons.

He did not resist the temptation of putting his impressions of national character, or as he put it, the "souls of nations," into print (1950). These essays, while not free of the generalizations and

exaggerations common to most writing of this sort, bring into focus the outstanding traits of each nation and are free of farfetched psychological conjectures.

Siegfried's writings on French political life fall into two categories: the historical studies of political regimes from the Third to the Fifth Republic and the ecological studies of political parties or tendencies. The latter include the early study of northwest France (1913) and the later one of Ardèche (1949a). These ecological studies represented a methodological innovation and were the beginning of a school of investigation that has gained adherents in many countries.

The observation that each of the major political tendencies in France has its particular strongholds which show a high degree of stability despite changing party labels led Siegfried to the conclusion that it was possible to distinguish regions of political opinion—political climates which correspond to regions in physical geography. The particular climate depends on the varying combinations of several major factors: (1) the social stratification of the regional population—whether it is egalitarian or hierarchic; (2) the religious orientation of the people—whether Roman Catholic or Protestant, and if Catholic, whether or not the political instructions of the priest are followed; (3) the past—that is, memories of important political events that influence political attitudes; (4) the extent to which the population is autochthonous or contains a significant proportion of "strangers" (in-migrants); (5) the geography—that is, the soil, the climate, the altitude, the topography, the settlement patterns, the population density, and the degree of accessibility or isolation of the area.

Siegfried's technique consisted essentially, although not exclusively, of comparing successive maps showing election returns by small areas with maps showing the geographic distribution of other factors and in assessing, from their fit, the relative importance of the various factors. For Ardèche, for example, the topographical map gave the best fit. In Ardèche ways of life vary with the altitude; the mountain, the hillside, and the plains communities are distinctly different. The merit of these ecological studies derives from Siegfried's intensive knowledge of the regions as well as from his sense of what is politically relevant. Although he used such formal notions as "the Right" and "the Left," he was careful to state what these mean in terms of immediate goals and general political ideas.

Although Siegfried held a chair of political and economic geography, he was not a geographer in the technical sense. The findings of geography and

geology were for him data essential to the understanding of society. Nor was he a geographical determinist, although he appreciated the opportunities and limitations which the physical environment offers to human action, particularly for the development of primary industries. The social structure, especially the class structure in the Marxian sense, depends on the use of these opportunities, and the class structure in combination with other factors produces certain political climates. But Siegfried was not a Marxist in his political orientation, or even a socialist. As a scholar, he felt obliged to avoid association with any political party. And yet, he was clearly a republican, a liberal, and a humanist and therefore also a social reformer.

While he had sympathy for the Anglo-Saxon style of political life, he regretted the "Americanizing" tendencies in the economic organization of France, the impending decline of the independent entrepreneur, and the replacement of the artisan-craftsman by the assembly-line worker. These tendencies, inescapable as they might be, he feared would endanger the dignity and spirituality of man.

## SIGNIFICANCE, TESTS OF

*The topic of significance testing is treated in detail in HYPOTHESIS TESTING, a term that is usually regarded as synonymous with "tests of significance," although some statisticians feel that there are important distinctions. The present article describes the basic ideas of significance testing, outlines the most important elementary tests, and reviews problems related to the philosophy and application of significance testing.*

Significance tests are statistical procedures for examining a hypothesis in the light of observations. Many significance tests are simple and widely used, and have a long history; the idea of significance testing goes back at least to the eighteenth century. There has been much confusion about significance testing, and consequently it has been much misused. Despite their apparent simplicity (and sometimes because of it), significance tests have generated many controversies about meaning and utility.

A significance test starts with observations and with a hypothesis about the chance mechanism generating the observations. From the observations a test statistic is formed. Large values of the test statistic (or small values, or both, depending on circumstances) lead to strong skepticism about the hypothesis, whereas other values of the test statistic are held to be in conformance with the hypothesis. Choice of the test statistic usually depends upon the alternatives to the hypothesis under test.

### Basic ideas

As an example of significance testing, suppose that the hypothesis under test, often called the *null hypothesis*, or  $H_0$ , is that sleep deprivation has no effect on a certain kind of human skill, say arithmetic ability as measured by a particular type of test. Some population must be specified; suppose

that it consists of all students at a particular college who are willing to participate in a sleep-deprivation experiment. One hundred students are chosen at random, tested for arithmetic skill, deprived of a night's sleep, and then tested again. For each student the initial test result minus the second test result is regarded as the basic observation, datum, or score. Suppose, for the present, that if the null hypothesis is false, the effect of sleep deprivation is either to increase average score or to decrease it; either direction might hold, so the *alternative hypotheses* are two-sided.

The analyst would, of course, be concerned about possible practice and motivational effects; a helpful device might be the use of a control group that would also be tested twice, but with a normal night's sleep. The effect of practice might be lessened by the presentation of a sequence of tests before the experiment proper begins. Another matter of concern is whether the basic score used, the *difference* between test results, is more appropriate than the ratio of test results or some other combination of them. For present purposes such issues are not discussed.

From the 100 scores a test statistic is then formed. The choice might well be the Student *t*-statistic, which is the observed average score divided by an estimate of its own variability. Details of the *t*-statistic are given later.

The nub of the significance-testing concept is that if the null hypothesis really is true, then it is unlikely that the Student *t*-statistic would be greater than, say, 2.6 in unsigned numerical value. The probability of that event, under the usual—but possibly dangerous—assumptions that the scores behave like statistically independent random variables with the same normal distribution, is about .01, or 1 out of 100. If, on the other hand, the null hypothesis is false, the probability of the event is greater than .01, much greater if sleep deprivation has a large effect.

Hence, if a Student *t*-statistic greater than 2.6 or less than -2.6 is observed, *either* the null hypothesis is false, *or* the null hypothesis is true and an event of small probability has occurred, *or* something is wrong with the underlying assumptions. If those assumptions seem satisfactory, and if the Student *t*-statistic is, say, 2.7, most people would prefer to act as if the null hypothesis were false. The cut-off number, 2.6, and the associated probability, .01, are cited for the sake of specific illustration. If 2.6 is replaced by a larger number, the associated probability is smaller; if it is replaced by a smaller number, the probability is larger.

In formal significance testing one decides beforehand on the cut-off number. If 2.6 is chosen, then there is a .01 probability of erroneously doubting the null hypothesis when it is in fact true.

In the example, 2.6 is called the *critical value* of the (unsigned) Student *t*-statistic, and .01 is called the *level of significance* or (usually synonymously) the *size* of the test. The level of significance, frequently denoted by  $\alpha$ , is also called the probability of Type I error, or of error of the first kind; this is the error of falsely doubting the null hypothesis when it is in fact true. In the present context, if the unsigned Student *t*-statistic turns out to be greater than the critical value, it is often said that the statistic (or the test, or the sample) is *statistically significant*; this terminology can lead to confusion, as will be described below.

From this approach, then, a significance test is a procedure, agreed upon beforehand, that will result in one of two conclusions (or actions, or viewpoints): if the test statistic—here the unsigned Student *t*-statistic—is greater than the critical value, one tends to act as if the null hypothesis is false; otherwise one tends to act in some different way, not necessarily as if the null hypothesis is true but at least as if its falsity is not proved. These two kinds of conclusions or actions are conventionally called, respectively, *rejection* and *acceptance* of the null hypothesis. Such nomenclature, with its emotional overtones and its connotations in everyday speech, has led to confusion and needless controversy. The terms "rejection" and "acceptance" should be thought of simply as labels for two kinds of actions or conclusions, the first more appropriate if the null hypothesis is false and the second more appropriate if it is true or at least not known to be false. In the example, rejection and acceptance might correspond to different attitudes toward a theory of sleep or to different recommendations for desirable amounts of sleep. (In some contexts, such as acceptance sampling in industry, the terms "acceptance" and "rejection" may be used literally.)

There is further room for confusion in the varying ways that significance testing is described. In the example it would be accurate to say that the hypothesis of no sleep-deprivation effect (on average score) is being tested. But it might also be said, more loosely, that one is testing the effect of sleep deprivation, and this might be misinterpreted to mean that the null hypothesis asserts a positive mean score under sleep deprivation. One reason for this ambiguity is that the null hypothesis is often set up in the hope that it will be rejected. In the comparison of a new medical treatment with an old one, equality of effectiveness might be un-

interesting, so only rejection of the null hypothesis of equality would excite the experimenter, especially if he had invented the new treatment. On the other hand, accepting the null hypothesis may itself be very important—for example, in an experiment to test the theory of relativity. Usually, however, there is a basic asymmetry between the null hypothesis and the other hypotheses.

The two-decision procedure discussed above is a highly simplified framework for many situations in which significance tests are used. Although there are cases in which the above viewpoint makes direct sense (for example, industrial acceptance sampling, crucial experiments for a scientific theory), most uses of significance tests are different. In these more common uses the analyst computes that level of significance at which the observed test statistic would just lead to rejection of the null hypothesis. In the example, if the observed Student *t*-statistic were 1.8, the resulting *sample level of significance*, or *observed significance level*, would be .075, again under the conventional assumptions listed earlier. From this second viewpoint the observed (or sample) significance level is a measure of rarity or surprise; the smaller the level, the more surprising the result if the null hypothesis is true. Naturally, if the result is very surprising under the null hypothesis, one is likely to conclude that the null hypothesis is false, but it is important to know quantitatively the magnitude of the surprise. The sample level of significance is often called the *P*-value, and the notation  $P = .075$  (or  $p = .075$ ) may be used. (For other views on measuring surprise, see Weaver 1948; Good 1956.)

Usually a very rough knowledge of the degree of surprise suffices, and various simplifying conventions have come into use. For example, if the observed significance level lies between .05 and .01, some authors say that the sample is *statistically significant*, while if it is less than .01, they call it *highly statistically significant*. The adverb "statistically" is often omitted, and this is unfortunate, since statistical significance of a sample bears no necessary relationship to possible subject-matter significance of whatever true departure from the null hypothesis might obtain (see Boring 1919).

From one point of view, significance testing is a device for curbing overenthusiasm about apparent effects in the data. For example, if the sleep-deprivation experiment showed a positive effect, an experimenter enthusiastic about a theory of sleep psychology might cry, "Eureka! Sleep deprivation really does have the predicted consequence." After he himself has had a good night's sleep, however, he might compute the appropriate test statistic and see, perhaps, that the observed effect—

or a greater one—could occur with probability .2 under the null hypothesis of no real underlying effect. This would probably dampen his initial enthusiasm and might prevent one of the many premature announcements of discoveries that clutter the literature of some sciences. (The sleep example is solely for illustration; I have no reason to think that experimenters on sleep are anything but cautious in their statistical analyses.)

On the other hand, it is easy to be overconservative and throw out an interesting baby with the nonsignificant bath water. Lack of statistical significance at a conventional level does not mean that no real effect is present; it means only that no real effect is clearly seen from the data. That is why it is of the highest importance to look at power and to compute confidence intervals, procedures that will be discussed later.

The null hypothesis, despite its name, need not be that the average effect of sleep deprivation is zero. One might test the null hypothesis that the average effect is 10 score units. Or one might test such a null hypothesis as: the average effect of sleep deprivation is not positive; or, again: the average effect lies between -10 and 10 score units. The last two null hypotheses, unlike the previous ones, do not fix the hypothesized average effect at a single value.

### Standard tests

There are a number of popular standard significance tests in the statistical armamentarium. The tests described here include those on means, variances, correlations, proportions, and goodness of fit.

**Mean.** The null hypothesis in a test on means, as in the original example, is that the expected value (mean) of a distribution is some given number,  $\mu_0$ . This hypothesis is to be tested on the basis of a random sample of  $n$  observations on the distribution; that is, one considers  $n$  independent random variables, each with that same distribution whose mean is of interest. If the variance,  $\sigma^2$ , of the distribution is known, and if  $\bar{X}$  denotes the sample mean (arithmetic average), a widely useful test statistic is

$$(1) \quad \frac{\bar{X} - \mu_0}{\sigma/\sqrt{n}},$$

which has mean zero and standard deviation one under the null hypothesis. Often the absolute (unsigned numerical) value of (1) is the test statistic. If the underlying distribution of interest is normal, then (1) is itself normally distributed, with variance one and mean zero (that is, it has a unit normal distribution) under the null hypothesis.

Even if the underlying distribution is not normal, (1) has approximately the unit normal distribution under the null hypothesis, provided that  $n$  is not too small.

In practice  $\sigma^2$  is usually unknown, and an estimator of it,  $s^2$ , is used instead. The most usual estimator is based on the sum of squared deviations of the observations from  $\bar{X}$ ,

$$(2) \quad s^2 = \frac{1}{n-1} [(X_1 - \bar{X})^2 + \cdots + (X_n - \bar{X})^2],$$

where the  $X_i$  are the observations. (The usual name for  $s^2$  is "sample variance," and that for  $s$  is "sample standard deviation.") Then (1) becomes the Student (or  $t$ -) statistic

$$(3) \quad \frac{\bar{X} - \mu_0}{s/\sqrt{n}}.$$

If the  $X_i$  are normal, then (3) has as its distribution under the null hypothesis the Student (or  $t$ -) distribution with  $n-1$  degrees of freedom ( $df$ ). If  $n$  is large (and often it need not be very large), then in quite general circumstances the distribution of (3) under the null hypothesis is approximately the unit normal distribution. [See DISTRIBUTIONS, STATISTICAL, articles on SPECIAL CONTINUOUS DISTRIBUTIONS and APPROXIMATIONS TO DISTRIBUTIONS.]

*Two samples.* Suppose that the observations form two independent random samples of sizes  $n_1$  and  $n_2$ :  $X_{11}, \dots, X_{1n_1}$  and  $X_{21}, \dots, X_{2n_2}$ . Here the first subscript denotes the sample (1 or 2), and the second subscript denotes the observation within the sample (1 through  $n_1$  or  $n_2$ ). For example, in the sleep-deprivation experiment the first sample might be of male students and the second of female students. The null hypothesis might be that the average effect of sleep deprivation on arithmetic skill is the same for male and female students. Note that this null hypothesis says nothing about the magnitude of the average effect; it says only that the average effect is the same for the two groups.

More generally, suppose the null hypothesis is that the two underlying means are equal:  $\mu_1 = \mu_2$ , where  $\mu_1$  is the expected value of any of the  $X_{1i}$  and  $\mu_2$  that of any of the  $X_{2i}$ . If the variances are known, say  $\sigma_1^2$  and  $\sigma_2^2$ , the usual test statistic is

$$(4) \quad \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}},$$

where  $\bar{X}_1$  and  $\bar{X}_2$  are the two sample means. If the  $X$ 's are normally distributed, (4) has the unit normal as null distribution—that is, as its distribution when the null hypothesis holds. Even if the  $X$ 's are

not normally distributed, the unit normal distribution is a good approximation to the null distribution of (4) for  $n_1, n_2$  large. (If, instead of the null hypothesis  $\mu_1 = \mu_2$ , one wishes to test  $\mu_1 = \mu_2 + \delta$ , where  $\delta$  is some given number, one need only replace  $\bar{X}_1 - \bar{X}_2$  in the numerator of (4) with  $\bar{X}_1 - \bar{X}_2 - \delta$ .)

If the variances are not known, and if  $s_1^2$  and  $s_2^2$  are estimators of them, a common test statistic is

$$(5) \quad \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}},$$

which, for  $n_1, n_2$  large, has the unit normal distribution as an approximation to the null distribution. The null distribution is better approximated by a  $t$ -distribution [details can be found in ERRORS, article on EFFECTS OF ERRORS IN STATISTICAL ASSUMPTIONS].

If the variances are unknown but may reasonably be assumed to be equal ( $\sigma_1^2 = \sigma_2^2$ ), then a common test statistic is the two-sample Student statistic,

$$(6) \quad \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2} \left( \frac{1}{n_1} + \frac{1}{n_2} \right)}},$$

where  $s_1^2, s_2^2$  are defined in terms of (2). If the observations are normally distributed, (6) has as null distribution the  $t$ -distribution with  $n_1 + n_2 - 2$   $df$ . This holds approximately, in general, if the  $X$ 's are mildly nonnormally distributed and if  $\sigma_1^2$  and  $\sigma_2^2$  differ somewhat but  $n_1$  and  $n_2$  are not very different.

*Paired samples.* The two-sample procedure described above should be distinguished from the paired two-sample procedure. The latter might be used if the subjects are fraternal twins of opposite sex, with both members of a sampled pair of twins observed. Then the male and female samples would no longer be independent, since presumably the members of a pair of twins are more nearly alike in most respects than are two random subjects. In this case one would still use  $\bar{X}_1 - \bar{X}_2$  in the numerator of the test statistic, but the denominator would be different from those given above. Although it is not always possible, pairing (more generally, blocking) is often used to increase the power of a test. The underlying idea is to make comparisons within a relatively homogeneous set of experimental units. [See EXPERIMENTAL DESIGN.]

[These significance tests, and generalizations of them, are further discussed in HYPOTHESIS TESTING; LINEAR HYPOTHESES, article on ANALYSIS OF VARIANCE; and ERRORS, article on EFFECTS OF ERRORS IN STATISTICAL ASSUMPTIONS.]

**Variances.** The null hypothesis in a test on variances may be that  $\sigma^2$  has the value  $\sigma_0^2$ ; then the usual test statistic is  $s^2$  as defined in (2), or, more conveniently,

$$(7) \quad (n-1)s^2/\sigma_0^2.$$

Under the null hypothesis, (7) has the chi-square distribution with  $n-1$  degrees of freedom, provided that the observations are normal, independent, and identically distributed. Unlike the null distributions for the tests on means, the null distribution of (7) is highly sensitive to deviations from normality.

In the two-sample case a common null hypothesis is  $\sigma_1^2 = \sigma_2^2$ . The usual test statistic is  $s_1^2/s_2^2$ , which, under normality, has as null distribution the  $F$ -distribution with  $n_1 - 1$  and  $n_2 - 1$  *df*.

[These tests are discussed further in LINEAR HYPOTHESES, article on ANALYSIS OF VARIANCE; VARIANCES, STATISTICAL STUDY OF.]

**Correlation.** The most common procedure in simple correlation analysis is to test the null hypothesis that the population correlation coefficient is zero, using as test statistic the sample correlation coefficient. Under the assumptions of bivariate normality and a random sample, the null distribution is closely related to a  $t$ -distribution. One can also test the null hypothesis that the population correlation coefficient has some nonzero value, say .55. Special tables or approximate methods are required here [see MULTIVARIATE ANALYSIS, articles on CORRELATION].

**Proportions. Single sample.** The simplest case in the analysis of proportions is that of a sample proportion and the null hypothesis that the corresponding population probability is  $p_0$ , some given number between 0 and 1. The sample proportion and population probability correspond to some dichotomous property: alive-dead, heads-tails, success-failure. It is convenient to summarize the sample in the form of a simple table

$N$	$n - N$	$n$
-----	---------	-----

where  $n$  is the sample size,  $N$  the number of sample observations having a stated property,  $n - N$  the number not having this property, and  $N/n$  the sample proportion. The usual sampling assumptions, which need examination in each application, are that the observations are statistically independent and that each has the same probability of having the stated property. As a result of these assumptions,  $N$  has a binomial distribution.

The usual test statistic is

$$(8) \quad \frac{N - np_0}{\sqrt{np_0(1-p_0)}},$$

which, for  $n$  not too small, has approximately the unit normal distribution under the null hypothesis. The square of this test statistic, again for  $n$  not too small and under the null hypothesis, has approximately a chi-square distribution with one *df*.

Notice that (8) is really a special case of (1) if  $N$  is regarded as the sum of  $n$  independent observations taking values 1 and 0 with probabilities  $p_0$  and  $1 - p_0$ .

**Two samples.** The data may consist of two sample proportions, and the null hypothesis may be that the corresponding population proportions are equal. It is convenient to express such data in terms of a  $2 \times 2$  table like Table 1, where the two samples (of sizes  $n_{1+}$ ,  $n_{2+}$ ) correspond to the upper two lines and the bottom and right rims are marginal totals—for example,  $N_{11} + N_{12} = n_{1+}$ . Capital letters denote random variables and lower-case letters nonrandom quantities. The usual assumptions, which must be examined in each application, are that  $N_{11}$  and  $N_{21}$  are independently and binomially distributed. A common test statistic is

$$(9) \quad \frac{(N_{11}/n_{1+}) - (N_{21}/n_{2+})}{\sqrt{\left(\frac{1}{n_{1+}} + \frac{1}{n_{2+}}\right) \frac{N_{+1}N_{+2}}{n^2}}},$$

which, for  $n$ 's not too small, has approximately the unit normal distribution under the null hypothesis. (Note the great similarity of test statistics (6) and (9), which are related in much the same way as (1) and (8).)

If the unsigned value of (9) is the test statistic, one may equivalently consider its square, which is expressible in the simpler form

$$(10) \quad n \frac{(N_{11}N_{22} - N_{12}N_{21})^2}{n_{1+}n_{2+}N_{+1}N_{+2}}.$$

Under the null hypothesis, and for  $n$ 's not too small, (10) has approximately a chi-square distribution with one *df*. Large values of (10) are statistically significant.

**Chi-square statistics.** The above test statistics, in squared form, are special cases of the chi-square test statistic; their null distributions are approxi-

Table 1 — Summary of two samples for analysis of proportions

	Number having property	Number not having property	Totals
Sample 1	$N_{11}$	$N_{12}$	$n_{1+}$
Sample 2	$N_{21}$	$N_{22}$	$n_{2+}$
Totals	$N_{+1}$	$N_{+2}$	$n_{++} = n$

mately chi-square ones. Such test statistics can generally be thought of in terms of data tabulations of the kind shown above; the statistic is the sum of terms given by the mnemonic expression

$$\frac{(\text{observed} - \text{"expected"})^2}{\text{"expected"}},$$

summed over the cells in the body of the table. For example, in the first, very simple table for a sample proportion, there are two cells in the body of the table, with  $N$  and  $n - N$  observed frequencies in them. The corresponding frequencies expected under the null hypothesis are  $np_0$  and  $n(1 - p_0)$ . Applying the mnemonic expression gives as the chi-square statistic

$$\frac{(N - np_0)^2}{np_0} + \frac{[n - N - n(1 - p_0)]^2}{n(1 - p_0)},$$

which can readily be shown to equal the square of (8). The one  $df$  for the approximate chi-square distribution is sometimes described thus: There are *two* observed frequencies, but they are restricted in that their sum must be  $n$ . Hence, there is *one*  $df$ .

Similarly, (10) can be obtained from the table for two proportions by means of the mnemonic expression. In this case the null hypothesis does not completely specify the expected frequencies, so they must be estimated from the data. That is why quotation marks appear around "expected" in the mnemonic. [Further details, and related procedures, including the useful continuity correction, are discussed in COUNTED DATA.]

**Association for counted data.** Suppose that the individuals in a sample of people are cross-classified by hair color and eye color, with perhaps five categories for each attribute. The null hypothesis is that the two attributes are statistically independent. A standard procedure to test for association in this *contingency table* is another chi-square test, which is based essentially on (10) above. Although the test statistics are the same and have the same approximate null distribution, the power functions are different. [This test and related ones are discussed in COUNTED DATA.]

**Nonparametric tests.** The tests for means, variances, and correlation, discussed above, are closely tied to normality assumptions, or at least to approximate normality. Analogous tests of significance, without the normality restriction, have been devised [these are discussed in NONPARAMETRIC STATISTICS; HYPOTHESIS TESTING].

**General approximation.** In many cases a test statistic,  $T$ , is at hand, but its null distribution is difficult to express in usable form. It is often useful to approximate this null distribution in terms of  $\mu_0$ , the expected value of  $T$  under the null hypothesis,

and  $S$ , an estimator of the standard deviation of  $T$  under the null hypothesis. The approximation takes  $(T - \mu_0)/S$  as roughly unit normal under the null hypothesis. This approximation is, intuitively and historically, very important. The first tests of proportions discussed above are special cases of the approximation.

**Goodness of fit.** A number of significance tests are directed to the problem of goodness of fit. In these cases the null hypothesis is that the parent distribution is some specific one, or a member of some specific family. Another problem often classed as one of goodness of fit is that of testing, on the basis of two samples, the hypothesis that two parent populations are the same. [See GOODNESS OF FIT.]

### Other aspects of significance testing

**Alternative hypotheses and power.** A significance test of a null hypothesis is usually held to make sense only when one has at least a rough idea of the hypotheses that hold if the null hypothesis does not; these are the *alternative hypotheses* (or *alternate hypotheses*). In testing that a population mean,  $\mu$ , is zero, as in the example at the start of the article, the test is different if one is interested only in positive alternatives ( $\mu > 0$ ), if one is interested only in negative alternatives ( $\mu < 0$ ), or if interest extends to both positive and negative alternatives.

When using such a test statistic as the Student  $t$ -statistic, it is important to keep the alternatives in mind. In the sleep-deprivation example the original discussion is appropriate when both positive and negative alternatives are relevant. The null hypothesis is rejected if the test statistic has either a surprisingly large positive value or a surprisingly large negative value. On the other hand, it might be known that sleep deprivation, if it affects arithmetic skill at all, can only make it poorer. This means that the expected average score (where the score is the initial test result minus the result after sleep deprivation) cannot possibly be negative but must be zero or positive. One would then use the so-called right-tail test, rejecting the null hypothesis only if the Student  $t$ -statistic is large. For example, deciding to reject  $H_0$  when the statistic is greater than 2.6 leads to a level of significance of .005. Similarly, right-tail  $P$ -values would be computed. If the Student statistic observed is 1.8, the right-tail  $P$ -value is .037; that is, the probability, under the null hypothesis, of observing a Student statistic 1.8 or larger is .037. There are also left-tail tests and left-tail  $P$ -values.

For a test considered as a two-action procedure, the *power* is the probability of (properly) rejecting the null hypothesis when it is false. Power, of

course, is a function of the particular alternative hypothesis in question, and *power functions* have been much studied. The probability of error of Type II is one minus power; a Type II error is acceptance of the null hypothesis when it is false. By using formulas, approximations, tables, or graphs for power, one can determine sample sizes so as to control both size and power. [See EXPERIMENTAL DESIGN, *article on THE DESIGN OF EXPERIMENTS*.]

A common error in using significance tests is to neglect power considerations and to conclude from a sample leading to "acceptance" of the null hypothesis that the null hypothesis holds. If the power of the test is low for relevant alternative hypotheses, then a sample leading to acceptance of  $H_0$  is also very likely if those alternatives hold, and the conclusion is therefore unwarranted. Conversely, if the sample is very large, power may be high for alternatives "close to" the null hypothesis; it is important that this be recognized and possibly reacted to by decreasing the level of significance. These points are discussed again later.

It is most important to consider the power function of a significance test, even if only crudely and approximately. As Jerzy Neyman wrote, perhaps with a bit of exaggeration, "... if experimenters realized how little is the chance of their experiments discovering what they are intended to discover, then a very substantial proportion of the experiments now in progress would have been abandoned in favour of an increase in size of the remaining experiments, judged more important" (1958, p. 15). [References to Neyman's *fundamental and pathbreaking contributions to the theory of testing* are given in HYPOTHESIS TESTING.]

There is, however, another point of view for which significance tests of a null hypothesis may be relevant without consideration of alternative hypotheses and power. An illuminating discussion of this viewpoint is given by Anscombe (1963).

**Combining significance tests.** Sometimes it is desirable to combine two or more significance tests into a single one without reanalyzing the detailed data. For example, one may have from published materials only the sample significance levels of two tests on the same hypothesis or closely related ones. (Discussions of how to do this are given in Mosteller & Bush [1954] 1959, pp. 328-331; and Moses 1956. See also Good 1958.) Of course, a combined analysis of all the data is usually desirable, when that is possible.

**Preliminary tests of significance.** A desired test procedure is often based on an assumption that may be questionable—for example, equality of the

two variances in the two-sample  $t$ -test. It has frequently been suggested that a preliminary test of the assumption (as null hypothesis) be made and that the test of primary interest then be carried out only if the assumption is accepted by the preliminary test. If the assumption is rejected, the test of primary interest requires modification.

Such a two-step procedure is difficult to analyze and must be carried out with caution. One relevant issue is the effect on the primary test of a given error in the assumption. Another is that the preliminary test may be much more sensitive to errors in other underlying assumptions than is the main significance test. [See ERRORS, *article on EFFECTS OF ERRORS IN STATISTICAL ASSUMPTIONS*. A discussion of preliminary significance tests, with references to prior literature, is given in Bancroft 1964. Related material is given in Kitagawa 1963.]

**Relation to confidence sets and estimation.** It often makes sense, although the procedure is not usually described in these terms, to compute appropriate sample significance levels not only for the null hypothesis but also for alternative hypotheses as if—for the moment—each were a null hypothesis. In this way one obtains a measure of how surprising the sample is for both the null and the alternative hypotheses. If parametric values corresponding to those hypotheses not surprising (at a specified level) for the sample are considered together, a *confidence region* is obtained. [See ESTIMATION, *article on CONFIDENCE INTERVALS AND REGIONS*.]

In any case, a significance test is typically only one step in a statistical analysis. A test asks, in effect, Is anything other than random variation appearing beyond what is specified by the null hypothesis? Whatever the answer to that question is—but especially if the answer is Yes—it is almost always important to estimate the magnitudes of underlying effects. [See ESTIMATION.]

**Relation to discriminant analysis.** Significance testing, historically and in most presentations, is asymmetrical: control of significance level is more important than control of power. The null hypothesis has a privileged position. This is sometimes reasonable—for example, when the alternative hypotheses are diffuse while the null hypothesis is sharp. In other cases there is no particular reason to call one hypothesis "null" and the other "alternative" and hence no reason for asymmetry in the treatment of the two kinds of error. This symmetric treatment then is much the same as certain parts of the field called discriminant analysis. [See MULTIVARIATE ANALYSIS, *article on CLASSIFICATION AND DISCRIMINATION*.]

### Dangers, problems, and criticisms

Some dangers and problems of significance testing have already been touched on: failure to consider power, rigid misinterpretation of "accept" and "reject," serious invalidity of assumptions. Further dangers and problems are now discussed, along with related criticisms of significance testing.

**Nonsignificance is often nonpublic.** Negative results are not so likely to reach publication as are positive ones. In most significance-testing situations a negative result is a result that is not statistically significant, and hence one sees in published papers and books many more statistically significant results than might be expected. Many—perhaps most—statistically nonsignificant results never see publication.

The effect of this is to change the interpretation of published significance tests in a way that is hard to analyze quantitatively. Suppose, to take a simple case, that some null hypothesis is investigated independently by a number of experimenters, all testing at the .05 level of significance. Suppose, further, that the null hypothesis is true. Then any one experimenter will have only a 5/100 chance of (misleadingly) finding statistical significance, but the chance that *at least one* experimenter will find statistical significance is appreciably higher. If, for example, there are six experimenters, a rejection of the null hypothesis by at least one of them will take place with probability .265, that is, more than one time out of four. If papers about experiments are much more likely to be published when a significance test shows a level of .05 (or less) than otherwise, then the nonpublication of nonsignificant results can lead to apparent contradictions and substantive controversy. If the null hypothesis is false, a similar analysis shows that the "power" of published significance tests may be appreciably higher than their nominal power. (Discussions of this problem are given in Sterling 1959; and Tullock 1959.)

**Complete populations.** Another difficulty arises in the use of significance tests (or any other procedures of probabilistic inference) when the data consist of a complete census for the relevant population. For example, suppose that per capita income and per capita dollars spent on new automobiles are examined for the 50 states of the United States in 1964. The formal correlation coefficient may readily be computed and may have utility as a descriptive summary, but it would be highly questionable to use sampling theory of the kind discussed in this article to test the null hypothesis that the population correlation coefficient

is zero, or is some other value. The difficulty is much more fundamental than that of nonnormality; it is hard to see how the 50 pairs of numbers can reasonably be regarded as a sample of any kind. Some statisticians believe that permutation tests may often be used meaningfully in such a context, but there is no consensus. [*For a definition of permutation tests, see NONPARAMETRIC STATISTICS. Further discussion of this problem and additional references are given in Hirschi & Selvin 1967, chapter 13. An early article is Woofter 1933.*]

**Target versus sampled populations.** Significance tests also share with all other kinds of inference from samples the difficulty that the population sampled from is usually more limited than the broader population for which an inference is desired. In the sleep-deprivation example the sampled population consists of students at a particular college who are willing to be experimental subjects. Presumably one wants to make inferences about a wider population: all students at the college, willing or not; all people of college age; perhaps all people. [*See STATISTICS; ERRORS, article on NON-SAMPLING ERRORS.*]

**Neglect of power by word play.** A fallacious argument is that power and error of the second kind (accepting the null hypothesis when it is false) need not be of concern, since the null hypothesis is never really accepted but is just not rejected. This is arrant playing with words, since a significance test is fatuous unless there is a question with at least two possible answers in the background. Hence, both kinds of probabilities of wrong answers are important to consider. Recall that "accept" and "reject" are token words, each corresponding to a conclusion that is relatively more desirable when one or another true state of affairs obtains.

To see in another way why more than Type I error alone must be kept in mind, notice that one can, without any experiment or expense, achieve zero level of significance (no error of the first kind) by never rejecting the null hypothesis. Or one can achieve any desired significance level by using a random device (like dice or a roulette wheel) to decide the issue, without any substantive experiment. Of course, such a procedure is absurd because, in the terminology used here, its power equals its level of significance, whatever alternative hypothesis may hold.

**Difficulties with significance level.** If significance tests are regarded as decision procedures, one criticism of them is based on the arbitrariness of level of significance and the lack of guidance in choosing that level. The usual advice is to examine

level of significance and power for various possible sample sizes and experimental designs and then to choose the least expensive design with satisfactory characteristics. But how is one to know what is satisfactory? Some say that if satisfaction cannot be described, then the experimenter has not thought deeply enough about his materials. Others oppose such a viewpoint as overmechanical and inappropriate in scientific inference; they might add that the arbitrariness of size, or something analogous to it, is intrinsic in any inferential process. One cannot make an omelet without deciding how many eggs to break.

*Unconventional significance levels.* Probably the most common significance levels are .05 and .01, and tables of critical values are generally for these levels. But special circumstances may dictate tighter or looser levels. In evaluating the safety of a drug to be used on human beings, one might impose a significance level of .001. In exploratory work, it might be quite reasonable to use levels of .10 or .15 in order to increase power. What is of central importance is to know what one is doing and, in particular, to know the properties of the test that is used.

*Nonconstant significance levels.* For many test situations it is impossible to obtain a sensible test with the same level of significance for all distributions described by a so-called composite null hypothesis. For example, in testing the null hypothesis that a population mean is not positive, the level of significance depends generally on the value of the nonpositive mean; the more it departs from zero, the smaller the probability of Type I error. In such cases the usual approach is to think in terms of the *maximum* probability of Type I error over all distributions described by the null hypothesis. In the nonpositive mean case, the maximum is typically attained when the mean is zero.

*Necessarily false null hypotheses.* Another criticism of standard significance tests is that in most applications it is known beforehand that the null hypothesis cannot be *exactly* true. For example, it seems most implausible that sleep deprivation should have literally no effect at all on arithmetic ability. Hence, why bother to test a null hypothesis known at the start to be false?

One answer to this criticism can be outlined as follows: A test of the hypothesis that a population mean has a specified value,  $\mu_0$ , is a simplification. What one really wants to test is whether the mean is *near*  $\mu_0$ , as near as makes no substantive difference. For example, if a new psychological therapy raises the cure rate from 51 per cent to 51.1 per cent, then even if one could discover such a small

difference, it might be substantively uninteresting and unimportant. For "reasonable" sample sizes and "reasonable" significance levels, most standard tests have power quite close to the level of significance for alternative hypotheses close to the null hypothesis. When this is so and when, in addition, power is at least moderately large for alternatives interestingly different from the null hypothesis, one is in a satisfactory position, and the criticism of this section is not applicable. The word "reasonable" is in quotation marks above because what is in fact reasonable depends strongly on context. To examine reasonableness it is necessary to inspect, at least roughly, the entire power function. Many misuses of significance testing spring from complete disregard of power.

A few authors, notably Hodges and Lehmann (1954), have formalized the argument outlined above by investigating tests of null hypotheses such as the following: The population mean is in the interval  $(\mu_0 - \Delta, \mu_0 + \Delta)$ , where  $\mu_0$  is given and  $\Delta$  is a given positive number.

There are, to be sure, null hypotheses that are not regarded beforehand as surely false. One well-known example is the null hypothesis that there is no extrasensory effect in a parapsychological experiment. Other examples are found in crucial tests of well-formulated physical theories. Even in these instances the presence of small measurement biases may make interpretation difficult. A minuscule measurement bias, perhaps stemming from the scoring method, in an extensive parapsychological experiment may give a statistically significant result although no real parapsychological effect is present. In such a case the statistical significance may reflect only the measurement bias, and thus much controversy about parapsychology centers about the nature and magnitude of possible measurement biases, including chicanery, unconscious cues, and biases of scoring.

A sharp attack on significance testing, along the lines of this section and others, is given by L. J. Savage (1954, chapter 16).

*Several tests on the same data.* Frequently, two or more hypothesis tests are carried out on the same data. Although each test may be at, say, the .05 level of significance, one may ask about the *joint* behavior of the tests. For example, it may be important to know the probability of Type I error for both of two tests together. When the test statistics are statistically independent, there is no problem; the probability, for example, that at least one of two tests at level .05 will give rise to Type I error is  $1 - (.95)^2 = .0975$ . But in general the tests are statistically dependent, and analogous compu-

tations may be difficult. Yet it is important to know, for example, when two tests are positively associated, in the sense that given a Type I error by one, the other is highly likely to have a Type I error.

When a moderate to large number of tests are carried out on the same data, there is generally a high probability that a few will show statistical significance even when all the null hypotheses are true. The reason is that although the tests are dependent, they are not completely so, and by making many tests one increases the probability that at least some show statistical significance. [*Some ways of mitigating these problems for special cases are described in LINEAR HYPOTHESES, article on MULTIPLE COMPARISONS.*]

**One-sided versus two-sided tests.** There has been much discussion in the social science literature (especially the psychological literature) of when one-sided or two-sided tests should be used. If a one-sided test is performed, with the choice of sidedness made tendentiously *after* inspection of the data, then the nominal significance level is grossly distorted; in simple cases the actual significance level is twice the nominal one.

Suppose that in the sleep-deprivation example the data show an average score that is positive. "Aha," says the investigator, "I will test the null hypothesis with a right-tail test, against positive means as alternatives." Clearly, if he pursues that policy for observed positive average scores and the opposite policy for observed negative average scores, the investigator is unwittingly doing a two-tail test with double the stated significance level. This is an insidious problem because it is usually easy to rationalize a choice of sidedness *post hoc*, so that the investigator may be fooling both himself and his audience.

The same problem occurs in the choice of test statistic in general. If six drugs are compared in their effects on arithmetic skill and only the observations on those two drugs with least and greatest observed effects are chosen for a test statistic, with no account taken of the choice in computing critical values, an apparently statistically significant result may well just reflect random error, in the sense that the true significance level is much higher than the nominal one. [*Some methods of dealing with this are described in LINEAR HYPOTHESES, article on MULTIPLE COMPARISONS.*]

**Three-decision procedures.** Many writers have worried about what to do after a two-tail test shows statistical significance. One might conclude, for example, that sleep deprivation has an effect on average score, but one wishes to go further and say that it has a positive or a negative effect, de-

pending on the sign of the sample average. Yet significance testing, regarded stringently as a two-decision procedure, makes no provision for such conclusions about sign of effect when a two-sided test rejects the null hypothesis.

What is really wanted in such a case may well be a *three-decision* procedure: one either accepts  $H_0$ , rejects  $H_0$  in favor of alternatives on one side, or rejects  $H_0$  in favor of alternatives on the other side. There is no reason why such a procedure should not be used, and it is, in effect, often used when the user says that he is carrying out a significance test. A major new consideration with this kind of three-decision procedure is that one now has *six*, rather than *two*, kinds of error whose probabilities are relevant; for each possible hypothesis there are two erroneous decisions. In some simple cases symmetry reduces the number of different probabilities from six to three; further, some of the probabilities may be negligibly small, although these are probabilities of particularly serious errors (for a discussion, see Kaiser 1960). A three-decision procedure may often be usefully regarded as a composition of two one-sided tests. [*See HYPOTHESIS TESTING.*]

A variety of other multiple-decision procedures have been considered, generally with the aim of mitigating oversimplification in the significance-testing approach. A common case is that in which one wants to choose the best of several populations, where "best" refers to largest expected value. [*A pioneering investigation along this line is Mosteller 1948. See also DECISION THEORY; SCREENING AND SELECTION.*]

**Hypotheses suggested by data.** In the course of examining a body of data, the analyst may find that the data themselves suggest one or more kinds of structure, and he may decide to carry out tests of corresponding null hypotheses from the very data that suggested these hypotheses. One difficulty here is statistical dependence (described above) between the tests, but there is a second difficulty, one that appears even if there is only a single significance test. In a sense, this difficulty is just a general form of the *post hoc* one-sided choice problem.

Almost any set of data, of even moderate size and complexity, will show anomalies of some kind when examined carefully, even if the underlying probabilistic structure is wholly random—that is, even if the observations stem from random variables that are independent and identically distributed. By looking carefully enough at random data, one can generally find some anomaly—for example, clustering, runs, cycles—that gives statistical significance at customary levels although no real effect

is present. The explanation is that although any particular kind of anomaly will occur in random data with .05 statistical significance just 5 times out of 100, so many kinds of anomalies are possible that at least one will very frequently appear. Thus, use of the same data both to suggest and to test hypotheses is likely to generate misleading statistical significance.

Most sets of real data, however, are not completely random, and one does want to explore them, to form hypotheses and to test these same hypotheses. One can sometimes use part of the data for forming hypotheses and the remainder of the data to examine the hypotheses. This is, however, not always feasible, especially if the data are sparse. Alternatively, if further data of the same kind are available, then one can use the earlier data to generate hypotheses and the later data to examine them. Again, this approach is not always possible.

As an example, consider one of the earliest instances of significance testing, by Daniel Bernoulli and his son John in 1734, as described by Todhunter ([1865] 1949, secs. 394–397). Astronomers had noticed that the orbital planes of the planets are all close together. Is this closeness more than one might expect if the orbital planes were determined randomly? If so, then presumably there is a physical reason for the closeness. The Bernoullis first attempted to make precise what is meant by randomness; in modern terminology this would be specification of randomness as a null hypothesis. They then computed the probability under randomness that the orbital planes would be as close together as, or closer than, the observed planes. This corresponds to deciding on a test statistic and computing a one-tail *P*-value. The resulting probability was very small and the existence of a physical cause strongly suggested. [For biographical material on the Bernoullis, see BERNOULLI FAMILY.]

Todhunter, in his *History*, described other early instances of significance testing, the earliest in 1710 by John Arbuthnot on the human sex ratio at birth (the relevant sections in Todhunter [1865] 1949 are 343–348, 617–622, 888, 915, and 987). Significance testing very much like that of the Bernoullis continues; a geophysical example, relating to the surprising degree of land–water antipodality on the earth's surface, has appeared recently (Harrison 1966). The whole topic received a detailed discussion by Keynes ([1921] 1952, chapter 25). Up-to-date descriptions of astronomical theories about the orbital planes of the planets have been given by Struve and Zeberg (1962, chapter 9).

Quite aside from the issue of whether it is reasonable to apply probabilistic models to such unique

objects as planetary orbits (or to the 50 states, as in an earlier example), there remains the difficulty that a surprising concatenation was noted in the data, and a null hypothesis and test statistic fashioned around that concatenation were considered. Here there is little or no opportunity to obtain further data (although more planets were discovered after the Bernoullis and, in principle, planetary systems other than our sun's may someday be observable). Yet, in a way, the procedure seems quite reasonable as a means of measuring the surprisingness of the observed closeness of orbital planes. I know of no satisfactory resolution of the methodological difficulties here, except for the banal moral that when testing hypotheses suggested during the exploration of data, one should be particularly cautious about coming to conclusions. (In the Bayesian approach to statistics, the problem described here does not arise, although many statisticians feel that fresh problems are introduced [see BAYESIAN INFERENCE].)

An honest attempt at answering the questions, What else would have surprised me? Was I bound to be surprised? is well worthwhile. For example, to have observed planetary orbits symmetrically arranged in such a way that their perpendiculars nearly formed some rays of a three-dimensional asterisk would also have been surprising and might well be allowed for.

**Difficulties in determining reference set.** Some statisticians have been concerned about difficulties in determining the proper underlying reference probabilities for sensibly calculating a *P*-value. For example, if sample size is random, even with a known distribution, should one compute the *P*-value as if the realized sample size were known all along, or should one do something else? Sample size can indeed be quite random in some cases; for example, an experimenter may decide to deal with all cases of a rare mental disorder that come to a particular hospital during a two-month period. [Three papers dealing with this kind of problem are Barnard 1947; Cox 1958; and Anscombe 1963. See also LIKELIHOOD.]

Random sample sizes occur naturally in that part of statistics called sequential analysis. Many sequential significance testing procedures have been carefully analyzed, although problems of determining reference sets nonetheless continue to exist. [See SEQUENTIAL ANALYSIS.]

**Optional stopping.** Closely related to the discussion of the preceding section is the problem of optional stopping. Suppose that an experimenter with extensive resources and a tendentious cast of mind undertakes a sequence of observations and

from time to time carries out a significance test based on the observations at hand. For the usual models and tests, he will, sooner or later, reach statistical significance at any preassigned level, even if the null hypothesis is true. He might then stop taking observations and proclaim the statistical significance as if he had decided the sample size in advance. (The mathematical background of optional stopping is described in Robbins 1952.)

For the standard approach to significance testing, such optional stopping is as misleading and reprehensible as the suppression of unwanted observations. Even for an honest experimenter, if the sampling procedure is not firmly established in advance, a desire to have things turn out one way or another may unconsciously influence decisions about when to stop sampling. If the sampling procedure is firmly established in advance, then, at least in principle, characteristics of the significance test can be computed in advance; this is an important part of sequential analysis.

Optional stopping is, of course, relevant to modes of statistical analysis other than significance testing. It poses no problem for approaches to statistics that turn only on the observed likelihood, but many statisticians feel that these approaches are subject to other difficulties that are at least equally serious. [See BAYESIAN INFERENCE; LIKELIHOOD.]

**Simplicity and utility of hypotheses.** It is usually the case that a set of data will be more nearly in accord with a complicated hypothesis than with a simpler hypothesis that is a special case of the complicated one. For example, if the complicated hypothesis has several unspecified parameters whereas the simpler one specializes by taking some of the parameters at fixed values, a set of data will nearly always be better fit by the more complicated hypothesis than by the simpler one just because there are more parameters available for fitting: a point is usually farther away from a given line than from a given plane that includes the line; in the polynomial regression context, a linear regression function will almost never fit as well as a quadratic, a quadratic as well as a cubic, and so on.

Yet one often prefers a simpler hypothesis to a better-fitting more complicated one. This preference, which undoubtedly has deep psychological roots, poses a perennial problem for the philosophy of science. One way in which the problem is reflected in significance testing is in the traditional use of small significance levels. The null hypothesis is usually simpler than the alternatives, but one may be unwilling to abandon the null hypothesis unless the evidence against it is strong.

Hypotheses may be intrinsically comparable in ways other than simplicity. For example, one hypothesis may be more useful than another because it is more closely related to accepted hypotheses for related, but different, kinds of observations.

The theory of significance testing, however, takes no explicit account of the simplicity of hypotheses or of other aspects of their utility. A few steps have been made toward incorporating such considerations into statistical theory (see Anderson 1962), but the problem remains open.

**Importance of significance testing.** Significance testing is an important part of statistical theory and practice, but it is only one part, and there are other important ones. Because of the relative simplicity of its structure, significance testing has been over-emphasized in some presentations of statistics, and as a result some students come mistakenly to feel that statistics is little else than significance testing.

**Other approaches to significance testing.** This article has been limited to the customary approach to significance testing based on the frequency concept of probability. For other concepts of probability, procedures analogous to significance testing have been considered. [See BAYESIAN INFERENCE. An extensive discussion is given in Edwards et al. 1963.] Anscombe (1963) has argued for a concept of significance testing in which only the null hypothesis, not the alternatives, plays a role.

## SIMIAND, FRANÇOIS

François Simiand (1873-1935), French economist and economic historian, was born at Gières (Isère) to a large family of modest means. Like most members of his family, he became a teacher. At 20, he entered the École Normale Supérieure in

Paris, preparing first for his teacher's license and then for his *agrégation* in philosophy. He passed the *agrégation* in 1896 and was then admitted to the Fondation Thiers, newly opened to researchers. At that time Simiand became interested in sociology and attended the courses taught by Émile Durkheim and Lucien Lévy-Bruhl. He began work on a dissertation on miners' wages in France, and thenceforth his sociological orientation distinguished much of his work from that of his economist contemporaries.

When Simiand was at the École Normale, Parisian students were very much stirred up by the Dreyfus affair. He and his fellow students had several opportunities to hear lectures by the socialists Lucien Herr and Jean Jaurès, and like many other Normaliens Simiand came to have a lasting sympathy for socialism. With Herr, Charles Péguy, and Léon Blum he later founded a bookselling and publishing cooperative, the Librairie Georges Bellais, named for one of their friends. Simiand's principal task was to edit a popular series, the *Bibliothèque socialiste*, and to head a technical program for training personnel for the cooperative. Since he had to earn a living at the same time that he was joining in the battle for socialism, he took a position as librarian at the Ministry of Labor, established in 1906, where he performed the enormous task of providing the documentary resources necessary for the new bureau.

At this time Simiand wrote methodological discussions that were violently critical of the historians, particularly of Charles Seignobos. The best example is an article entitled "Méthode historique et science sociale," which appeared in the *Revue de synthèse historique* in 1903. Simiand rejected Seignobos' conception of history as a mere collection of political facts isolated from their social and economic context. Even such faithful friends as Paul Mantoux, however, could not accept Simiand's destructive conclusions. Simiand was also at work on his thesis, *Le salaire des ouvriers des mines de charbon en France*, which he defended in 1904 and published in a revised version in 1907. It was the forerunner of his later research on wages.

With the war of 1914 Simiand began a period of government service. His socialist connections led to his appointment as aide to Albert Thomas, who became undersecretary of state for artillery and munitions in 1915. Simiand continued in government service until 1920. He worked strenuously to organize war production; later he saw to it that the transition from the German to the French regime in Alsace-Lorraine was carried out in such a way that the people of those provinces retained the social gains they had made before 1918.

In 1920 Simiand resigned his administrative functions and from then on devoted himself entirely to study and teaching. In 1910 he had been called to the École Pratique des Hautes Études as lecturer in the history of economic theory. After 1920 he resumed teaching there, and in 1924 he became chairman of the department of history and economic statistics. At the same time he also taught at the Conservatoire National des Arts et Métiers, as professor of labor organization and labor unions from 1919 to 1923 and as professor of political economy from 1923 to 1933. In 1932 he succeeded Georges Renard as professor of labor history at the Collège de France. Simiand's health, already impaired by his work during the war, could not stand the intense pace of his activity. He died at Saint-Raphael (Var) in 1935.

This final period, from about 1930 to 1935, was intellectually Simiand's most fruitful one, and his publications were numerous. He published the lectures he gave at the Conservatoire, which clearly show the development of his economic thinking. He also produced works inspired by the world crisis—a set of lectures given at the University of Brussels on long-term economic fluctuations (1932a) and a study of economic development in the United States, in which economic analysis is related to historical factors (1934).

Most important, Simiand completed the master-work to which he had devoted so much of his life, his research on price movements and wages (1932b). He prefaced the work by a long methodological introduction, explaining his particular interest in the study of wages. Wages, he asserted, are a social reality, and it was by the use of economics that he hoped to grasp social realities of this kind. Furthermore, wages are an empirical entity: they can be dealt with statistically; they correspond to a real value; they are part of an economic and social complex. Accordingly, wages appear to be made to order as a subject for the kind of scientific investigation advocated by Simiand, namely one that applies the methods of the natural sciences to the social sciences. As he saw the study, the methodological procedures gradually emerged from the study itself and were not established by a conceptual system nor did they follow preconceived ideas. Simiand believed that he had thus found a new method for studying economic facts, but his ideas found no followers, and he remained an isolated figure.

#### SIMMEL, GEORG

Georg Simmel (1858–1918), German philosopher and sociologist, is still a controversial figure. While some hail him as the founder of modern sociology, others see in him only a brilliant stylist who made no original contribution and failed to develop a systematic theory. It is true that Simmel was no system builder and was often preoccupied with defining approaches—philosophical, historical, or sociological—which he illustrated with his substantive analyses. But these analyses, subtle and full of surprising insights, still delight and stimulate readers, while many of the more systematic works of his contemporaries are no longer read.

**Life and career.** Simmel's life was externally uneventful. He spent most of it in Berlin, his native

city; he traveled little; and he experienced neither true poverty nor wealth, neither unanimous rejection nor great success. His predominant preoccupations were intellectual. He was not immediately concerned with the acute social and political problems of his age, and only once did a political event, the outbreak of World War I, move him to deep and emotional concern. His intellectuality was passionate, and he had a strong disdain for everything crude and vulgar, reflecting a kind of spiritual aristocracy.

Simmel's father was a Jewish businessman who had become a Roman Catholic; his mother was of Jewish origin but a Lutheran. Simmel, baptized as a Lutheran, later renounced his church membership but retained a philosophical interest in religion. While he was still in school, his father died. His guardian later left him a small fortune, which enabled Simmel to live as a scholar even when he was without a salaried academic position. He studied history, folk psychology, the history of art, and philosophy at the University of Berlin, where he received his doctorate in 1881. His dissertation on the philosophy of Kant gained a prize; the thesis he wrote for his subsequent habilitation also dealt with Kant. He started to lecture as a *Privatdozent* in 1885 and almost immediately attracted large and enthusiastic audiences. At first he lectured on philosophy and ethics, but soon he began to emphasize certain sociological aspects of his topics and later devoted whole courses to this new subject, which at that time was not being taught by anyone else at his university. However, sociology accounted for only about half of his course offerings.

In 1890 Simmel married. His wife, Gertrud, with whom he had one son, was also intellectually inclined and a writer on philosophy. Their home became a meeting place for members of Berlin's intellectual elite. But in his academic career Simmel was long frustrated, apparently because of his Jewish origin, his nonprofessorial brilliance, and his intellectual attitude, which some felt to be destructive. It was 15 years before he even became titular professor, and all attempts to achieve a full professorship failed until, at the age of 56, he was finally called to a chair at the University of Strassburg in 1914. He died there of cancer in the fall of 1918.

**Influence.** Simmel may be remembered today primarily by sociologists, but for him sociology was only one of many interests, and his productive period in this field lasted barely more than one decade. His earliest and his latest works were philosophical. He had a lifelong interest in art, admired and wrote about Rodin, received the young

Rilke in his home, published a book about Goethe, and was a friend of Stefan George. Simmel's bibliography (Gassen & Landmann 1958) lists 31 books (some very short ones), 256 articles, essays, etc. (many published in nonscholarly journals), and about 100 translations of his works into other languages.

Thus, Simmel was well known during his lifetime. However, he did not found a "school" in any of his fields of work. In philosophy his reputation did not long survive his death; in the 1920s his work was already overshadowed by existential philosophy. In sociology, Tönnies praised him during his lifetime, Durkheim published one of his essays in *L'année sociologique*, and Max Weber, whom he joined in founding the German Sociological Society in 1910, esteemed him and in his own later work utilized some of Simmel's concepts and theses. However, both Durkheim and Weber soon surpassed Simmel in influence and renown, and later only Leopold von Wiese followed the path outlined by Simmel, although even von Wiese coupled his explicit indebtedness with criticism.

In the United States, Simmel first became known through early translations, many of them by Albion W. Small, and through the efforts of Park and Burgess (1921) and Spykman (1925). But the impact was not deep. After a period of oblivion, the efforts of Kurt H. Wolff (see *The Sociology of Georg Simmel*; Simmel 1908a; Wolff 1959) and Rudolph H. Weingartner (1962) have revived some interest in Simmel, but with a few exceptions, such as Coser's book on conflict (1956) and the work of several authors on the three-person group (the triad), Simmel's analyses have not been explicitly followed up by modern sociologists.

Simmel himself foresaw this fate when he wrote in his diary that he would leave no spiritual heirs because his heritage would be dispersed and made use of as money is used. And indeed, much of his sociological thought has become common coin without remaining associated with his name.

**Intellectual ancestors.** Simmel was sensitive to the intellectual currents of his time and reflected most of them in his work without identifying himself exclusively with any one of them. His methodology is fashioned according to Kantian principles, but with modifications. He was influenced by Hegel, Schopenhauer, and Nietzsche, and his philosophy of life—foreshadowing modern existentialism—has noticeable affinities with the work of his friend Husserl and of Bergson. The influence of Dilthey can be found in both Simmel's sociology and his cultural philosophy, notably in his views on differentiation, interaction (*Wechselwirkung*), and

the individual. Spencer, Comte, and Marx were other influences on Simmel's sociology, but he rejected contemporary positivism and social Darwinism, and he was definitely not a Marxist. Thus, the work of Simmel escapes easy classification.

**Philosophical position.** For Simmel, philosophy was not a discipline ranged alongside other disciplines. Philosophy both precedes and follows all special disciplines—as epistemology, on the one hand, and as philosophy of the particular object, on the other. Philosophy, then, is not constituted by and confined to a particular subject matter; it is a distinct mode of treating any given subject matter, characterized by receptiveness to the totality of being and at the same time expressive of a fundamental attitude or world orientation on the part of the philosophizing person. Simmel demonstrated this view by writing on the philosophy of such different objects as money, culture, the sexes, religion, and art.

Epistemologically, Simmel held, in the manner of Kant, that all experience of contents is shaped by a priori categories. This view is the basis for his distinction between form and content, which later also became the methodological principle for his sociology. The distinction is clearly analytical. Form is, first of all, a basic organizing principle of perception or modality of experience, which imparts structure to that which in its immediate unity is structureless. Not simply philosophy itself, but also religion and science, are modalities of experience that may be applied alternatively to the same content.

Simmel extended this view to history. History is not the exact reproduction of all that has happened and is happening, but a coherent representation of the boundless manifold of human life and its products, created by selective perception and ordering. At first Simmel held this to be true not only for historiography but also for the conscious experience of history; later he modified this view somewhat and found a certain intrinsic coherence in history itself as a process of life. But Simmel did not stipulate any specific selective principle as adequate to the historical mode of perception, and it was this relativism that Troeltsch criticized as excessive historicism. Simmel never worked as a historian in the usual sense, although he had a widely ramified knowledge of history and often drew on it for illustrations, especially in his sociological works—including as sociological his *Philosophie des Geldes* (1900a).

Simmel's philosophies of life and of culture may be considered together as one coherent, substantive theory. Life as a force or principle was for him a

process of unbounded continuity, an uninterrupted flowing, a creative movement: life is more-life, as he put it. As a principle, life is the opposite of form and alien to it. But as a concrete process, life can become real only in forms. The individual, the concrete subject of life, is himself a bounded creature, and individual experience gives form to contents, thereby creating the objects of external reality. This process of objectification has two aspects: the perception of objects as external and the production of objects of material and spiritual culture (e.g., law, systems of knowledge, art, religion). Here Simmel talked of life as more-than-life, life becoming real and expressing itself in the creation of objects. These objects he also called "forms," a duplication of terms that may easily cause confusion.

As a continuous and creative process, life cannot be contained in finished and static forms (or objects). It must leave and destroy them, but only to crystallize again in new forms. This is the basic antinomy of life, which becomes the tragedy of culture when attention is turned to the fate of the individual in this process. The individual produces objects of culture to maintain his life and develop his potentialities. To this end he must not only utilize the sum total of human products (or objective spirit), but he must also interiorize them and reintegrate them into the stream of his life. But this reintegration of subject and object remains unachievable. The elements of objective spirit, as finished forms dissociated from the stream of life, possess their own dynamic. They become autonomous and develop according to their inner logic, no longer means but ends in themselves. Thus, if man first wanted to know in order to live, some men will later live only to accumulate more knowledge. In the end, man is dominated and enslaved by his own products.

The parallel to the dialectic theory of alienation is obvious. But if for Marx alienation can be resolved in a future society, for Simmel the contradiction flowing from the antinomy of life is eternal. Naturally, Marxist critics jumped on this. Thus, in a brilliant critique, Lukács (1953) accused Simmel of promoting a cynical and complacent adjustment to the *status quo* by interpreting as eternal a condition of the individual that is characteristic only of imperialism.

Simmel's conception of the process of culture is not completely ahistorical. As he noted especially in the *Philosophie des Geldes* (1900a), social differentiation and the attendant specialization of human activities greatly increase the production of cultural objectifications. Thus, at the same time

that specialization makes the full development of personality ever more difficult, there is a steadily growing amount of objective culture to be interiorized if subjective (or personal) culture is to flourish. Accordingly, the discrepancy between objective and subjective culture appears largest in contemporary society, where it has given rise to a struggle not only against obsolete forms, but against form as a principle.

The development of individual personality is a concern that links Simmel's philosophy with his sociology. In the latter, he came to a more positive conclusion. While the full realization of individual personality is impeded by the tragedy of culture, it is also promoted by social differentiation and the expansion of social groups, and potentially even by the growth of a money economy.

**The process of social development.** Simmel's theory of social development, although presented in his sociological writings, can be considered apart from his "pure" or "formal" sociology. In viewing this process, Simmel used two distinct points of reference, or approaches. The first, linked to his view of the process of culture, considers social differentiation and group expansion chiefly from the point of view of the effects on individualization.

Social differentiation and the quantitative expansion of groups are seen to be closely interrelated. Small groups are more vulnerable and cannot make full use of the energy-saving principle of division of labor; hence their preservation requires greater involvement and effort on the part of each member. With the expansion of groups and increasing differentiation, a lesser involvement is sufficient—and is all that can be demanded, since the consensus in larger groups tends to become segmental. Also, with group expansion the relations between members become impersonal, guided by an order of abstract rules. Thus only a limited and clearly defined contribution comes to be expected of each member, and this results in greater personal freedom. At the same time individuality has a chance to increase: as groups form on the basis of segmental interest and partial involvement, each person tends to belong to a larger number of different groups, and this has an individualizing effect.

The development of a money economy contributes to individualization both directly and indirectly, by stimulating the growth of large and purposive groups. Money is the basis of impersonal social relations and permits the substitution of financial for personal obligations. Of all types of obligation, a merely financial one is most compat-

ible with a maximum of personal freedom—although this is, of course, freedom only in the negative sense, or potential freedom, which must be used for personal development. As money makes the individual independent of particular persons and groups, it stimulates the formation of associations for limited and specific purposes and hence contributes to the growth and multiplication of groups with the attendant individualizing effect.

Simmel saw a close relationship between the existence of a money economy, rationality, and the growth of natural science. All three are based on the principle of calculation. Rational (i.e., purposive and calculating) action presupposes knowledge of causal relations and hence motivates the search for such knowledge. As a consequence of such pervasive rationalization, emotionalism decreases; this, on the one hand, means a shallower emotional life but, on the other hand, facilitates mutual understanding and conciliation.

Simmel's second approach in considering the process of group expansion and social development would today be called functionalist. It derives from the influence of Spencerian evolutionism, which marked Simmel's view on social differentiation as put forth in his first sociological publication (1890). There he stated that the development of organisms is directed by a tendency toward greater efficiency, or as he put it, toward a relative saving of energy. This tendency is, according to Simmel, the characteristic, and positive, consequence of social differentiation, and he took great pains to demonstrate this principle in the growth of various forms of higher social organization—not very convincingly for the modern reader. In fact, Simmel dropped this evolutionary thesis later and did not repeat it in his other sociological works. But he retained the basic principle implied in this thesis—the explanation of certain social forms, processes, and changes by their usefulness.

Simmel's functionalism pervades all his sociological work, but it is perhaps most prominent in his treatment of the self-preservation of social groups, where he discussed the conditions for the continuous existence of a group in spite of a constant turnover of members—among these conditions are functional differentiation and formation of specialized organs, symbols, and norms, and formalization or impersonality in the definition of duties and obligations. However, here at least Simmel escaped the danger of organismic reification, which threatens any attempt to explain the rise or persistence of something by its usefulness to the group or social system. In his book on social differen-

tiation (1890) he had stated explicitly that the observable tendencies toward group maintenance—such as group defense mechanisms—are not independent forces inherent in the group as such. Rather, they result from the self-interest of the members in preserving the group, because group solidarity is a necessity for individual life, especially in situations of conflict and strife. By virtue of social-psychological mechanisms, which Simmel only sometimes treated explicitly, the solidarity thus created tends to survive its immediate causes, giving existing groups a greater stability.

**Relationism and the concept of society.** One of Simmel's basic tenets is that all things are to be considered as interdependent, or as functions of each other. This view, referred to as his functionalism, relativism, or, most appropriately, relationism, should be clearly distinguished from his specifically sociological functionalism, which, by contrast, went largely unnoticed until recently. Simmel's relationism derives from his basic philosophical position that reality is essentially movement, continuity, process, and that only the human intellect, fashioned to serve as an instrument for action and not for gaining knowledge for its own sake, tends to perceive reality in terms of structures and substances—solid, fixed phenomena that are amenable to classification, ordering, and calculation. But what is thus commonly regarded as a substance is often essentially a process, a function, an interdependence.

This view is most pronounced in Simmel's treatment of money and of society. For Simmel money is not in itself a valuable substance and therefore exchangeable for objects of all sorts; it is, on the contrary, essentially the action of exchange in a concrete form, the material expression of the exchange relationship, a social function become a substance [see INTERACTION, *article on SOCIAL INTERACTION*].

Simmel similarly rejected the view that society is a substance, an organism, an irreducible real entity. Society is nothing but the sum total of the interactions and interdependencies (the German term *Wechselwirkung* implies both) between individuals—whose unity in turn is constituted only by the interaction between parts. Understandably, this view of society met with criticism from authors such as Othmar Spann, who resented this dissolution of the social organism and charged Simmel with psychologizing sociology. In fact, Simmel's explicit reference in his definition of society to Kant's treatment of nature may be misleading. But society was for him not merely a psychic phenom-

enon, a phenomenon of perception, because its constituents—interactions and interdependencies—are real enough. Only the conception of society as an entity is a matter of perception.

**The nature of sociology.** Simmel's lasting attractiveness as a sociological author may derive from the subtlety of his substantive analyses, but his most important contribution is, nevertheless, usually considered to be his methodology, which gave an independent status to sociology as a special discipline. Simmel rejected sociology as a comprehensive study of all social facts, since as such it would be only a label for numerous special disciplines treating different aspects of the same general object, human life and its products. But if sociology has no concrete object of its own, it nevertheless gains a special object of cognition by isolating analytically the aspect of interaction from the whole of social reality. Interactions are to be analyzed not only where they have crystallized into relatively permanent structures or social institutions, but also on the level of the more transitory interpersonal relations. This emphasis on the sub-institutional, or microsociological, was novel for his time.

Simmel was also impatient with the confusion between sociology and the philosophy of history or social philosophy, and he wanted sociology to keep close to observable phenomena, leaving all metaphysical interpretations that transcend objective knowledge to what he later (1917) called "philosophical sociology." However, Simmel did not conceive of sociology in a positivistic fashion, as a science of laws. He had early rejected the use of natural science as a model for the disciplines dealing with man and his creations, and he did not side with the positivists in the hotly debated issue of the idiographic as against the nomothetic character of social science. Rather, he attempted to play down any such distinction by pointing out that both viewpoints are alternative modes of perception. But the search for social laws never appeared promising to him. As early as 1890 he wrote that since a given event may have several and alternative causes, so that it can be produced by varying constellations of factors, it is usually impossible to formulate rules about a lawful association of isolated variables. When he himself described some specific regularity in his substantive analyses he repeatedly pointed out that this was not to be taken as a "law," but only as a descriptive generalization, leaving quite open which causes might produce it under varying conditions. Simmel expressly denied the existence of laws of social

development or of history in general and once even suggested that what we now know as natural laws may at some later time be revealed to be superstitions. Lukács (1953) has charged that this "struggle against law and causality" was the self-defense of imperialistic philosophy against dialectical materialism and that with it Simmel undermined objective scientific knowledge.

Of course, Simmel did not reject the possibility of causal explanation in the realm of human life and its products. But such explanation was for him essentially psychological in nature. Ultimately, the genesis of specific social forms and cultural objectifications must be derived psychologically. In his substantive analyses, Simmel again and again offered psychological explanations for the phenomena he described, both in terms of the conscious motives, interests, or goals of the individuals involved, and in terms of unconscious psychic mechanisms determining the reactions of these individuals. But he did not draw on any systematic psychological theory; rather, his often strikingly sensitive and perceptive explanations seem the result of introspection and conjecture.

**Formal sociology.** In 1890 Simmel defined the subject matter of sociology as consisting of interactions and interrelations, but he did not remain content with this definition. Later, going back to the basic distinction made in his philosophy, he demanded that the forms of interaction be distinguished from their contents and held that only the former constitute sociology's special object of cognition. Still later (1917), this seems to have appeared too restrictive to him, and he conceived of a "general sociology" in addition to formal sociology; but he failed to make its approach clear.

The contents of interaction are its motive powers—individual drives, purposes, interests, and so forth. The forms of interaction, or social forms, are not structured real entities (analogous to the forms of culture) but abstract, analytical aspects of social reality. They might best be conceived of as basic structural configurations or structuring principles. Simmel found a justification for this distinction in the seeming independence of forms and contents: the same structural principle can be observed in groups or relations characterized by widely divergent contents, while the same content (interest, purpose) may be found expressed in different forms of social organization.

Simmel's attempt to explain the concept of social form with a misleading analogy between sociology and geometry and his admitted failure to make his methodological principle quite explicit did much to provoke criticism of his "formal sociol-

ogy." Such criticism was especially directed against the form-content distinction, on the grounds that in social reality the structural details of any concrete group and its particular syndrome of "contents" are inseparably linked. This is true and, incidentally, is quite obvious from Simmel's own analyses. But Simmel expressly distinguished the forms of sociation from their embodiment in special social units. Conceived of as very general, abstract structural principles, or basic modes of interrelationship among social elements, the forms of sociation can indeed be isolated analytically. Structural principles that Simmel himself named are the relation of superordination-subordination; the relation of antagonism (conflict); the division of labor, or relation of functional interdependence; the ingroup-outgroup relation and the related principle of party formation; the principle of representation; the principles of spatial and temporal structuring; and the quantitative dimension. Other structural principles are implied in Simmel's writings, such as the dependence-autonomy dimension, which plays such a crucial role in his analysis of group membership and individuality.

The specific task of sociology was for Simmel not the causal explanation of these social forms, but the analysis of their objective meaning. This distinction is analogous to one commonly made in the analysis of forms of culture, such as objects of art and systems of ideas: they possess an *objective meaning*, which is something distinct from their psychologically explained genesis. The objective meaning (the analogy does not fit completely) of social forms rested for Simmel in their essential characteristics and range of empirical variation, on the one hand, and in their consequences, on the other. His *Soziologie* (1908b) contains several chapters devoted to the analysis of selected structural principles in these terms. In other chapters he started by focusing on a specific type of group (e.g., secret societies) or class of persons (e.g., the stranger, the poor man, the aristocrat) and proceeded to show how they are characterized and determined by a unique constellation of several of these structural principles.

Where Simmel dealt with the essential characteristics of some social form, his writing has a strongly phenomenological flavor. But the inclusion of the consequences or effects of social forms breaks this confinement and links his formal approach with his theory of social development, since he selected for analysis the consequences of given structural configurations either for individualization or for the preservation and functioning of groups. This procedure is obvious not only in the

topical chapters on these subjects, but also where he treated specific structural principles (e.g., conflict), special types of relationship, such as marriage, or special types of groups, such as secret societies. Thus his *Soziologie*, often criticized for being an unsystematic collection of substantive analyses only vaguely connected with his formal approach, really does possess a surprising—if partly implicit—internal coherence.

**Norms and individual behavior.** Simmel occasionally used the term "role" and recognized that social relations are defined by mutual obligations. Yet it would be a mistake to interpret his social forms as structures in the Parsonian sense, i.e., basically normative patterns, or to see the influence of social forms on individual behavior as that of role expectations. When Simmel analyzed individual behavior, he saw it primarily as a result of individual motives and of psychologically mediated reactions to the structure of the situation. He would not have denied that norms also play a part in determining individual behavior, but he paid little attention to them on this level of analysis. This may be due to his often paramount psychological interest and to the fact that he did not conceive of norms as external constraints or impositions. The latter view is made explicit in his *Lebensanschauung*, or philosophy (1918a), where he maintained that *Sollen*—a substantivation of the German verb meaning "shall" for which there is no exact translation—is a basic mode of life, a "categorical archphenomenon." Its specific contents, however, are to be derived psychologically and historically.

This last view seems connected with the fact that when Simmel argued sociologically, on the group level instead of on the individual level, he paid more explicit attention to norms. And here, the "historical" determination of the content of norms appears to be essentially of a functionalistic nature. In 1890 he had stated that what is "correct behavior" changes with the expansion of the group, and from several examples he used for illustration it becomes clear that the content of a norm, be it law or custom, depends on its social usefulness. Similar examples can be found in his later sociological works. But the whole principle is never explicitly stated as such, and the criterion of usefulness is not defined precisely; sometimes it seems to be goal achievement, sometimes group preservation, and sometimes it is the facilitation of a process of development.

**Ahistorical nature of formal sociology.** One of the major criticisms of Simmel's approach is directed at its ahistorical nature. Of course, Simmel

did not deny the historical character of society, which he saw as a continuous process, the present always being shaped by the accumulated past. But it seems that by selecting the forms of interaction for analysis, he defined as the essence of society that which is changeless and ahistorical, thus freezing history into motionless structures by his mode of perception.

That he conceived of the forms of sociation as abstract, general principles is undeniable. He used them to *describe* historical forms of social organization and certain general aspects of social development, but he did not use them to *explain* social phenomena as stages in a historical process. His focus on basic structural characteristics even made him occasionally describe as permanent some social form or relation that we would recognize as historically relative. This is true, for instance, of his description of sociability as a pure form of sociation, which might be roughly identified as an upper-bourgeois culture pattern, or of his analysis of the characteristics of man and woman, which is in effect largely a generalization of culturally relative sex roles.

The question is whether these examples merely point to occasional errors in Simmel's search for truly general ahistorical structuring principles or whether he failed—whether he *had* to fail—in this effort throughout. For it might be argued that since social reality is always historical in nature, nothing but historical forms can be abstracted from it. If this were true, even Simmel's most general structural principles, like antagonism, superordination, and so forth, would be specific to a certain phase of history and inapplicable in others. Simmel did not think so, which means that as a matter of principle he thought it possible to abstract ahistorical concepts or analytical dimensions from social reality. While the majority of contemporary sociologists would tend to share his view, it is this methodological position which, in the last analysis, defines Simmel as ahistorical in the eyes of modern dialectic theory.

## SIMONDE DE SISMONDI, J. C. L.

Jean Charles Léonard Simonde de Sismondi (1773-1842), historian and economist, was born in Geneva, Switzerland. His father was a Protestant clergyman who had married the daughter of a well-to-do Genevan family. At the age of 16, when Sismondi was a clerk in Eynard's Bank at Lyons, he witnessed the first tremors of the French Revolution. The revolution had repercussions in Geneva, and the family sought refuge in England, returning in 1794 but moving again soon after-

ward to a farm at Pescia, Italy. After his return to Geneva in 1800, Sismondi wrote his *Tableau de l'agriculture toscane*, which appeared the following year. In 1803 he published his book *De la richesse commerciale*, as a result of which he was offered the chair of political economy at the University of Vilna, with a salary of 6,000 francs. Sismondi declined the offer, having decided to devote his energies to his great *Histoire des républiques italiennes du moyen âge*, the 16 volumes of which appeared over the period 1809–1818.

In 1804/1805, Sismondi accompanied Madame de Staël on her voyage to Italy, along with August Wilhelm von Schlegel and other celebrities who frequented her chateau at Coppet, eight miles northeast of Geneva. In 1807/1808, the same group traveled in Germany and Austria, where the baroness took pleasure in introducing Sismondi to her aristocratic friends. Before long, he began to receive handsome royalties for his history of the Italian republics as well as fees for his numerous articles. The Geneva aristocracy, which had earlier turned its back on Sismondi because, during the Revolution, his father had been seen taking the milk of his cows to market (*Fragments . . .*, p. 70), now offered him a professorship at the university. Again, Sismondi declined.

Unfortunately, a valuable source of information on Sismondi's life and opinions seems to have been lost. It is believed that after his death some of his correspondence was burned by his widow and by the marquess of Bossi, his executor.

Sismondi's reputation as a historian and political writer spread rapidly, and during the Hundred Days he had an interview with Napoleon himself, whose constitutional program he defended. After the Restoration, Sismondi resumed work on his history of the Italian republics and, having seen the last volume through the press, threw himself at once into a still vaster project, his *Histoire des Français*; by the time of his death in 1842, 29 volumes had appeared, and two more were published posthumously.

For the modern student, Sismondi's most important work is his *Nouveaux principes d'économie politique* (1819). Jettisoning the viewpoint he had adopted earlier in his *Richesse commerciale* (1803), Sismondi pointed out in his new book that the supporters of the free-trade doctrine were in pursuit of a false prosperity: the *laissez-faire* policy recommended by Say, Ricardo, Malthus, and McCulloch, and followed by the British government, while increasing material wealth, diminished the amount of enjoyment at the disposal of each individual, and as a result of this policy the

wealthy grew wealthier and the poor grew poorer, more dependent, even destitute. The book was translated at once into Italian, but reaction elsewhere in Europe was slow, except in England, where it took a rather unexpected form.

There is ample evidence that at the time that Sismondi released his *Nouveaux principes*, in the spring of 1819, Malthus had been working on his *Principles of Political Economy* for years, without being sure whether, or when, he was going to be able to finish it. The volume was to have been ready in December 1817 but did not come off the press until April 1820. What speeded up Malthus' work between these two dates was surely the publication of Sismondi's book. A comparison of the two books shows that all of Sismondi's important ideas reappear, sometimes in a slightly different garb, in Malthus' *Principles*, which contains references both to Sismondi and to John Barton, a young British economist who, working independently, had reached similar conclusions [see the biography of BARTON]. Ricardo read Malthus' work as soon as it was available. He noticed the name of Barton, remembered the correspondence he had previously exchanged with him, and revised his own doctrine in the light of the arguments originally presented by Sismondi and Barton and now by Malthus. This resulted in the addition to Ricardo's *Principles of Political Economy and Taxation* (see 1817) of the famous 31st chapter "On Machinery" (added in the 1821 edition), in which the author virtually abandoned the free-trade doctrine he had advocated until then. However, Ricardo was not aware of the full significance of his change of mind, for after a meeting he had with Sismondi at Coppet in 1822 he wrote that "after a long battle we each of us, I believe, remained in the same opinion that we commenced the discussion in" (*Works*, vol. 9, p. 248).

Sismondi was respected by men like Ricardo and Barton; but according to Cavour, who made his acquaintance while in Geneva, Sismondi was not a strong debater and could not put up an effective defense against the attacks of men like the economist Antoine E. Cherbuliez. In later years, bourgeois writers usually commented favorably on Sismondi's literary talent, while glossing over his criticism of free-trade doctrine. Socialist writers made use of this criticism, sometimes without giving credit where it was due. Karl Marx, while borrowing copiously from Sismondi's critical analysis of free trade, attacked him as an "economic romanticist." Lenin also attacked Sismondi, and more violently than Marx did.

From the perspective of the twentieth century

Sismondi has proved to have been more perceptive than most free-traders and more realistic than most nineteenth-century socialists.

#### SIMONS, HENRY C.

Henry Calvert Simons (1899-1946), American economist, spent most of his professional career at the University of Chicago, teaching in the department of economics and then becoming the first professor of economics in the law school. He de-

veloped a unified and comprehensive set of principles of economic policy for the United States and applied these principles to the changing problems of his times.

Simons called his philosophy libertarian; the essential requirement of a good political and economic order is that it protect, promote, and respond to the free choices of individuals. However, what is distinctive about his philosophy is the combination of this idea with two others: First, a merely negative, "hands-off" policy of government is not sufficient to maintain the free economic order and realize its benefits; the government must undertake certain limited but important affirmative actions. (The title of his first work to gain national attention, "A Positive Program for Laissez-faire," 1934, already conveyed this idea, and it recurs throughout his writing.) Second, equality is a value only a little below freedom.

Simons' important writings began to appear in 1933 and 1934, near the bottom of the great depression. The failure of "free enterprise" and laissez-faire had greatly strengthened support for government intervention in economic activity. There were no apparent limits to the character and scope of these interventions, less because of any widespread acceptance of a policy of extensive government control than because of the absence of any principles for distinguishing between controls that were necessary, appropriate, or feasible and those that were not.

Simons proposed a set of principles for making this distinction: It is the responsibility of the government to maintain a framework within which a free economy can successfully operate and to do so by means that are general in their application, impersonal, and based on law rather than administrative discretion. But the government should not intervene in the heart of the economic process—in the determination of relative prices and wages and in production and investment decisions. Specifically, Simons emphasized the government's responsibility for maintaining appropriate monetary and competitive conditions.

Simons believed that the failure of the government to discharge its responsibility for maintaining reasonable stability in the supply of money had been one of the main causes of the severity of the depression. He was an early leader, among American economists, in advocating monetary expansion, to be achieved by means of budget deficits, as the road to recovery from the depression. But he did not believe that it was sufficient merely to assign to the government the responsibility of using its monetary, fiscal, and debt-management policies

to achieve some vaguely defined goal of economic stability. Reform of the banking system was also necessary, and he urged that the money supply be based on a 100 per cent reserve of government obligations. Also, he argued the case for a statutory rule of monetary policy that would govern the conduct of the monetary authorities. Which of several reasonable rules was chosen was less important than the existence of some objective standard known to the public and binding on the authorities.

Simons often argued against what he considered excessively loose, discretionary, and expansionist prescriptions by overenthusiastic advocates of positive fiscal and monetary policy. Yet, the more important fact is that Simons, the champion of free enterprise and nonintervention, did accept and emphasize the responsibility of the government to use its monetary and fiscal policies affirmatively to stabilize the economy. This allowed Simons and his followers to influence policy more than they could have done if they had denied government responsibility. Simons was among the first to stress that if federal tax rates were unchanged, the resulting decline of revenues in recessions and rise of revenues in booms would have a strong stabilizing influence on the economy; that varying the revenue side of the budget might be a more effective fiscal instrument than varying the expenditure side; and that the way in which the government financed its debt would be a significant independent economic factor. These ideas all became important in postwar fiscal thinking and fiscal policy. Thus, Simons' writings made a major contribution to the emergence of a postwar consensus on fiscal and monetary policy in the United States, not only among economists but also among persons in government and in the private economy whose opinions were influential.

While Simons believed that monetary stability is a necessary background condition for the effective operation of the free economy, he also felt that competition is the active driving force of the economy. He relied upon competition to organize production efficiently; to promote technological advance and economic growth; to permit high employment without inflation; to provide individuals, as consumers and as sellers of productive services, with the real alternatives that are the essence of freedom; to yield "commutative justice," in the sense of economic rewards proportional to productive contributions; to prevent extreme inequality of power or income; and to minimize the need for government intervention to settle conflicts between private interests.

In his early writings Simons seemed to believe

that the degree of competition in the United States was far from adequate to serve these purposes, chiefly because corporations had been permitted to grow to excessive size. Later, Simons' view of the problem changed. He came to believe that it was the trend toward monopoly, rather than the degree of monopoly already achieved, that was the great danger. Moreover, the natural force of competition was strong, so strong that private arrangements, unaided by government, could only temporarily and partially suppress it. Therefore, the first requirement was to prevent government from supporting monopoly.

In his last writings, including "Some Reflections on Syndicalism" (1944), which became the classic statement of the case against trade unions, Simons argued that unions were the principal threat to the competitive, and therefore free, society. Simons offered no confident remedy, only the hope that awareness of the danger would make it possible to limit the growth of union power before it was too late.

The part of his program that Simons elaborated in greatest detail was the tax system. His two longest (although relatively short) works, *Personal Income Taxation* (1938) and *Federal Tax Reform* (written in 1943, published 1950), were on this subject. Simons' writing on taxation largely spelled out the implications of a few basic ideas, the one most closely identified with his name being the definition of income, for tax purposes, as the sum of consumption plus the change in the value of net assets owned. Other ideas fundamental to his thinking about taxes were (a) that all taxation is taxation of individuals and must be judged by its effects on individuals; (b) that the allocation of income to short periods of time, like a year, is arbitrary and causes injustice and inefficiency; and (c) that in taxation, as in other policies, the government should avoid accidental or deliberate interference with the system of relative prices and wages. Rigorous application of these ideas enabled Simons to cut through a great deal of sophisticated argument about such matters as capital gains, gifts and bequests, corporate profits, and tax-exempt securities. Twenty years after his death, the considerations contained in Simons' work were still basic to the continuing effort to rationalize the federal income tax system.

It was in his tax proposals that Simons' stress on equality as a social goal found its most immediate expression. Simons did not believe that policy for reducing inequality should be confined to creation of a progressive tax system, but he did believe that correction of the tax system had to

come first. As he said, "There are remarkable opportunities for extending the range of socialized consumption (medical services, recreation, education, music, drama, etc.) and especially for extending the range of social welfare activities. The prospects in these directions, however, must remain somewhat unattractive as long as the expenditures involved must be covered by the kinds of taxes on which we have relied in the past—that is, so long as what the government gives to the masses with one hand is largely taken away with the other" ([1934] 1948, pp. 68–69).

Irma Adelman  
Charles F. Hermann

### I

#### INDIVIDUAL BEHAVIOR

"Simulation" is a term now generally employed to denote an approach to the construction of theories that makes essential use of computers and computer-programming languages. In some appli-

cations simulation techniques are used in investigating formal mathematical theories—for example, stochastic learning theories. In other applications, the theoretical models of the systems that are simulated are essentially nonquantitative and non-numerical.

We may define simulation more specifically as a method for analyzing the behavior of a system by computing its time path for given initial conditions, and given parameter values. The computation is said to "simulate" the system, because it moves forward in time step by step with the movement of the system it is describing. For the purposes of simulation, the system must be specified by laws that define its behavior, during any time interval, in terms of the state it was in at the beginning of that interval.

Simulation has always been an important part of the armory of applied mathematics. The introduction of modern computers, however, has so reduced the cost of obtaining numerical solutions to systems of equations that simulation has taken on vastly increased importance as an analytic tool. As a consequence, the relative balance of advantage has shifted from simplifying a theory in order to make it solvable toward retaining complexity in order to increase its accuracy and realism. With simulation and other techniques of numerical analysis, computers permit the study of far more complicated systems than could have been investigated at an earlier time.

Simulation with mathematical theories. Consider first the simulation of systems that are described by mathematical models (Newell & Simon 1963a, pp. 368–373). A model consists of a system of equations containing variables, literal constants (often called parameters), and numerical constants. The system of equations may be solved symbolically, by expressing the several variables explicitly in terms of the literal and numerical constants; or the system may be solved numerically, by substituting particular numerical values for the literal constants and then solving the equations for these special cases. For many complex systems of equations, symbolic solutions cannot be obtained, only numerical solutions. The former are clearly preferred when obtainable, for once a symbolic solution has been found, the special cases are readily evaluated by substituting numerical values for the parameters in the solutions instead of in the original equations.

To take a highly simplified example, a learning theory might postulate that the rate at which learning occurs is proportional to the amount of material

remaining to be learned. If, for simplicity of exposition, we divide time into discrete intervals and define the variable  $x(t)$  as the amount of material that has been learned up to the end of the  $t$ th time interval, then the theory can be expressed by a simple difference equation:

$$(1) \quad x(t+1) - x(t) = a[b - x(t)],$$

where  $a$  is a literal constant that we can name intelligence for this learning task, and  $b$  is a literal constant that represents the total amount to be learned. The symbolic solution to this simple system is well known to be:

$$(2) \quad x(t) = b - [b - \bar{x}(0)](1 - a)^t,$$

where  $\bar{x}(0)$  is a literal constant denoting the amount that had already been learned up to the time  $t = 0$ . Particular numerical solutions can now be found by assigning numerical values  $a$ ,  $b$ , and  $\bar{x}(0)$  and by solving (2) for  $x(t)$  for any desired values of  $t$ . Alternatively, numerical solutions—learning curves—for the system can as readily be computed for given  $a$ ,  $b$ , and  $\bar{x}(0)$  directly from equation (1), transferring the  $x(t)$  term to the right-hand side and solving successively for  $x(1)$ ,  $x(2)$ ,  $x(3)$ ,  $\dots$ . This latter procedure—solving (1) numerically—would be called simulation.

The advantages of simulation as a technique for analyzing dynamic systems are not evident from the excessively simple equation (1). Suppose, however, that  $a$ , instead of being a literal constant, designated some function,  $a[b, x(t)]$ , of  $b$  and  $x(t)$ . Only for very special cases could (1) then be solved symbolically to obtain an explicit expression, like (2), for  $x(t)$ . In general, when we wish to know the time paths of systems expressed by such equations, numerical solution for special cases—that is, simulation—is our main recourse.

A great many of the mathematical theories currently used for the study of learning and other individual behavior are probabilistic or stochastic in character. Such theories pose formidable mathematical problems, and explicit symbolic solutions for their equations are seldom obtainable. Unlike a deterministic system, the solution of the equations of a stochastic system does not specify a single time path for the system but assigns a probability distribution to all possible paths of the system. In some cases, certain properties of this probability distribution—certain means and variances—can be obtained symbolically, but the specification of the entire probability distribution can seldom be obtained symbolically. In order to estimate the parameters of the distribution numerically, the

system can be simulated by Monte Carlo techniques. That is, random variables can be introduced into the model, and the equations analogous to (1) solved a number of times, each time with different values of the random variables assigned and using the appropriate probabilities. The numerical solutions to (1) will trace out *possible* paths of the system, and the probability that a particular path will be followed in the simulation will be proportional to its probability under the assumptions of the model. Then, from the numerical results of the Monte Carlo simulation, numerical estimates can be made of the parameters of the probability distribution. [See RANDOM NUMBERS.]

**Information-processing theories.** The greatest use of simulation for the study of individual behavior has involved so-called information-processing theories, which are different in important respects from classical mathematical theories. Simulation has exactly the same relation to information-processing theories as to other formal theories—it is a method for discovering how the system described by the theory will behave, in particular circumstances, over a period of time. However, almost no methods other than simulation exist for investigating information-processing theories. For this reason, a phrase like “simulation of cognitive processes” often refers both to an information-processing theory of cognitive processes and to the investigation of the theory by simulation, in the narrower sense of the term. [See INFORMATION THEORY.]

Information-processing theories of individual behavior take the form of computer programs, usually written in programming languages called list-processing languages, especially devised for this purpose. The information-processing theories undertake to explain how a system like the human central nervous system carries out such complex cognitive processes as solving problems, forming concepts, or memorizing. The explanation is sufficiently detailed to predict—by computer simulation—behavior in specific problem situations. That is to say, the theory aims at predicting, not merely some quantitative aspects of behavior (number of errors in a learning situation, for example), but the actual concrete behaviors and verbal outputs of subjects placed in the very same situation and confronted with the identical task. [See CONCEPT FORMATION; PROBLEM SOLVING.]

A specific example will help make clear exactly what is meant by this. Clarkson (1963) has constructed an information-processing theory to ex-

plain how a bank officer selects portfolios of securities for trust funds. The trust officer, who has been told the purpose of the trust and the amount of money available for investment, prepares a list of stocks and bonds that can be bought with this sum. If the computer program is provided (as input) the same information about the purpose of the trust and its size, it will also produce (as output) a list of stocks and bonds. A first test of the program, as a theory, is whether it will pick the same list of companies and the same number of shares in each as the trust officer. In an actual test, for example, the program predicted the trust officer would buy 60 shares of General American Transportation, 50 Dow Chemical, 10 IBM, 60 Merck and Company, and 45 Owens-Corning Fiberglas. The trust officer in fact bought 30 Corning Glass, 50 Dow Chemical, 10 IBM, 60 Merck and Company, and 50 Owens-Corning Fiberglas.

A second and more severe test of the theory is whether, in reaching its final choices, it goes through the same stages of analysis, weighs the same factors, considers the same alternatives, as the human it is simulating. As one technique for making this kind of test, the human subject is asked to perform the task while thinking aloud, and his stream of verbalizations (protocol) is recorded. The human protocols are then compared with the *trace* produced by the computer program while it is performing the same task (for an example of this technique, which Clarkson also used, see Newell & Simon 1963b).

Omar K. Moore and Scarvia B. Anderson (1954) devised a task that required the subject to "recode" certain symbolic expressions. One problem was to recode  $L1: (r \supset -p) \cdot (-r \supset q)$  into  $L0: -(-q \cdot p)$ . (For purposes of the experiment and of this example, these strings of symbols can be treated as "code messages," whose meaning need not be known. The expression  $L1$  may be read "parenthesis  $r$  horseshoe minus  $p$  parenthesis dot parenthesis minus  $r$  horseshoe  $q$  parenthesis.") The recoding had to be carried out according to certain rules, which were numbered from 1 to 12. At one point in his thinking-aloud protocol, a subject said, "Now I'm looking for a way to get rid of the horseshoe inside the two brackets that appear on the left and right side of the equation. And I don't see it. Yeah, if you apply rule 6 to both sides of the equation, from there I'm going to see if I can apply rule 7."

The same recoding task, recoding  $L1$  into  $L0$  according to the rules specified by Moore and Anderson, was given to a program, the General Problem Solver (GPS), expressing an information-

processing theory of human problem solving. One portion of the trace produced by the program read as follows:

Goal: Apply rule 7 to  $L1$ .

Subgoal: Change "horseshoe" to "wedge" in left side of  $L1$ .

Subgoal: Apply rule 6 to the left side of  $L1$ .

Result:  $L4: (\neg r \vee \neg p) \cdot (\neg r \supset q)$ .

Subgoal: Apply rule 7 to  $L4$ .

Subgoal: Change "horseshoe" to "wedge" in right of  $L4$ .

Subgoal: Apply rule 6 to right side of  $L4$ .

Part of the test of the adequacy of GPS as a theory of human problem solving would be to decide how closely the segment of the human protocol reproduced above corresponded to the segment of the computer trace. For example, in the illustrative fragment cited here, both the human subject and GPS went down a blind alley, for rule 7 turned out to be not applicable to the expression recoded by rule 6. A theory of human problem solving must predict and explain the mistakes people make, as well as their ability sometimes to achieve solutions.

Information-processing theories can also be tested in more orthodox ways than by comparing protocols with traces. A program can be simulated in an experimental design identical with one that has been employed for human subjects. Statistics from the computer runs can be compared with the statistics of the human performance. This is the principal means that has been used to test the Elementary Perceiver and Memorizer (EPAM), an information-processing theory of human rote learning that will be described briefly later (Feigenbaum 1963). By having EPAM learn nonsense syllables by the standard serial anticipation method, at various simulated memory drum speeds and for lists of different lengths, quantitative predictions were made of the shape of the so-called serial position curve (relative numbers of errors during the learning process for different parts of the list of syllables). These predictions showed excellent agreement with the published data from human experiments. In other experiments in the learning of paired nonsense syllables, EPAM predicted quantitatively the effects upon learning rate of such variables as degree of familiarity with the syllables and degree of similarity between syllables. These predictions also corresponded closely with the published data from several experiments. [See FORGETTING and LEARNING, article on VERBAL LEARNING.]

In summary, an information-processing theory is expressed as a computer program which, exactly like a system of difference or differential equations, predicts the time path of a system from given initial conditions for particular values of the system parameters. The theory predicts not merely gross quantitative features of behavior but the actual stream of symbolic outputs from the subject. Such theories can be subjected to test in numerous ways; among others, by comparing the behaviors, including the thinking-aloud protocols, of subjects with the computer traces produced by the simulating programs.

**Evaluation.** The examples reveal both some of the strengths and some of the difficulties in the information-processing approach to theory construction and theory testing. On the positive side, the theories are written in languages that are capable of representing stimuli and responses directly and in detail, without an intermediate stage of translation into mathematical form. This has the further advantage of avoiding virtually all problems of stimulus scaling. The stimuli themselves, and not scales representing some of their gross characteristics, serve as inputs to the theory. Although the computer traces produced by the simulations are not in idiomatic English, the comparison of trace with protocol can be handled by relatively unambiguous coding techniques.

One of the main difficulties of the approach is closely related to one of its strengths—the detail of its predictions. Since different human subjects do not behave in exactly the same way in identical task situations, a simulation that predicts correctly the detail of behavior of one individual will predict the detail of behavior of others incorrectly. Presumably, a theory of individual behavior should consist of general statements about how human beings behave, rather than statements about how a particular human being behaves. At a minimum we would want to require of a theory that modifications to fit the behaviors of different subjects should change only relatively superficial features of the theory—values of particular parameters, say—and that they not necessitate fundamental reconstruction of the whole simulation program. It remains to be seen how fully this requirement will be met by information-processing theories. Up to the present, only a modest amount of investigation has been made of the possibilities of creating variants of simulation programs to fit different subjects.

Generality is needed, too, in another direction. Most of the early simulation programs were constructed to explain human performance in a single

task—discovering proofs for theorems in symbolic logic, say, or making moves in chess. It seems unreasonable to suppose that the programs a human uses to solve problems in one task environment are entirely specific to that environment and separate and independent from those he uses for different tasks. The fact that people can be scaled, even roughly, by general intelligence argues against such total specialization of skills and abilities. Hence, an important direction of research is to construct theories that can be applied over a wide range of tasks.

An example of such a theory is GPS, already mentioned. GPS can simulate behavior in any problem environment where the task can be symbolized as getting from a given state of affairs to a desired state of affairs. A wide range of problem-solving tasks can be expressed in this format. (To say that GPS can simulate behavior in any such environments means, not that the program will predict human behavior correctly and in detail, but that the program can at least be made to operate and produce a prediction, a trace, in that environment, for comparison with the human behavior.)

Thus, GPS has actually been given tasks from about a dozen task environments—for example, discovering proofs for theorems in logic, solving the missionaries-and-cannibals puzzle, and solving trigonometric identities—and there is every reason to suppose it can handle a wide range of others.

**Levels of explanation.** There has been great diversity of opinion in individual psychology as to the appropriate relation between psychological theory and neurophysiology. One extreme of the behaviorist position holds that the laws of psychology should state functional relations between the characteristics of stimulus situations, as the independent variables, and response situations, as the dependent variables, with no reference to intervening variables. A quite different position holds that explanation in psychology should relate behavior to biological mechanisms and that the laws of psychology are essentially reducible to laws of neurophysiology.

Information-processing theories represent a position distinct from either of these (Simon & Newell 1964). Unlike the extreme behaviorist theories, they make strong assumptions about the processes in the central nervous system (CNS) that intervene between stimulus and response and endeavor to explain how the stimulus produces the response. On the other hand, the information-processing theories do not describe these intervening processes in terms of neurophysiological mechanisms but postulate much grosser elements: symbol struc-

tures and elementary information processes that create and modify such structures and are, in turn, controlled by the structures.

Behaviorist theories may be called one-level theories, because they refer only to directly observable phenomena. Neurophysiological theories are two-level theories, for they refer both to behavioral events and underlying chemical and biological mechanisms. Information-processing theories are at least three-level theories, for they postulate elementary information processes to explain behavior, with the suggestion that the elementary information processes can subsequently be explained (in one or more stages of reduction) in chemical and biological terms. [See LEARNING, *article on NEUROPHYSIOLOGICAL ASPECTS*; and NERVOUS SYSTEM.]

Elementary information processes and symbol structures play the same role, at this intermediate level of explanation, as that played by chemical reactions, atoms, and molecules in nineteenth-century chemistry. In neither case is it claimed that the phenomena cannot be reduced, at least in principle, to a more microscopic level (neurophysiology in the one case, atomic physics in the other); it is simply more convenient to have a division of labor between psychologists and neurophysiologists (as between chemists and atomic physicists) and to use aggregative theories at the information-processing level as the bridge between them.

**Some specific theories.** The remainder of this article will be devoted to an account of the psychological substance of some current information-processing theories of cognition. Because space prohibits a complete survey of such theories, the examples will be restricted to problem solving, serial pattern recognition, and rote memory processes. Theories of other aspects of pattern recognition and concept formation will be omitted (Hunt 1962; Uhr 1966), as will be theories proposing a parallel, rather than serial, organization of cognitive processes (Reitman 1965).

The theories to be described are incorporated in a number of separate programs, which have not yet been combined into a single information-processing theory of "the whole cognitive man." Nevertheless, the programs have many similar components, and all incorporate the same basic assumptions about the organization and functioning of the CNS. Hence, the theories are complementary and will be discussed here, not as separate entities, but as components of a theory of cognition (Simon & Newell 1964).

The basic assumptions about the organization and functioning of the CNS are these:

(1) The CNS contains a *memory*, which stores

symbols (discriminable patterns) and composite structures made up of symbols. These composite structures include *lists* (ordered sets of symbols, e.g., the English alphabet) and *descriptions* (associations between triads of symbols). The relation "black, opposite, white," to be translated "white is the opposite of black," is an example of a description.

(2) The CNS performs certain *elementary processes* on symbols: storing symbols, copying symbols, associating symbols in lists and descriptions, finding symbols on lists and in descriptions, comparing symbols to determine whether they are identical or different.

(3) The elementary processes are organized hierarchically into *programs*, and the CNS incorporates an *interpretive process* capable of executing such programs—determining at each stage what elementary process will be carried out next. The interpretation is serial (not all information-processing theories share this assumption, however), one process being executed at a time.

The memory, symbol structures, elementary processes, and interpreters are the information-processing mechanisms in terms of which observed human behavior is to be explained. Programs constructed from these mechanisms are used to simulate problem solving, memorizing, serial pattern recognizing, and other performances.

**Problem-solving processes.** A central task of any theory of human problem solving is to explain how people can find their way to solutions while exploring enormous "mazes" of possible alternative paths. It has been calculated that if a chess player were to consider all the possible outcomes of all possible moves, he would have to examine some  $10^{120}$  paths. In fact he does not do this—obviously he could not, in any event—but conducts a highly selective search among a very much smaller number of possibilities. Available empirical data indicate that a problem solver usually explores well under a hundred paths in this and other problem-solving "mazes."

Experiments based on information-processing theories have shown that such selective searches can be accomplished successfully by programs incorporating rules of thumb, or heuristics, for determining which paths in the maze are likely to lead to solutions (Feigenbaum & Feldman 1963, part 1, secs. 2, 3). Some of the heuristics are very specific to a particular task environment. As a person becomes skilled in such an environment, he learns to discriminate features of the situation that have diagnostic value, and he associates with those features responses that may be appropriate in situa-

tions of the specified kind. Thus, an important component in specific skills is a "table of connections," stored in memory, associating discriminable features with possibly relevant actions. For example, a chess player learns to notice when the enemy's king is exposed, and he learns to consider certain types of moves (e.g., "checking" moves) whenever he notices this condition. [See ATTENTION.]

Much of the behavior of problem solvers in chess-playing and theorem-proving tasks can be explained in terms of simple "feature-noticing" programs and corresponding tables of connections, or associations. But the programs must explain also how these components in memory are organized into effective programs for selective search. These organizing programs are relatively independent of the specific kind of problem to be solved but are applicable instead (in conjunction with the noticing processes and associations) to large classes of task environments. They are general heuristics for problem solving.

The central GPS heuristic is an organization of elementary processes for carrying out *means-end analysis*. These processes operate as follows: the symbolized representations of two situations are compared; one or more differences are noted between them; an operator is selected among those associated with the difference by the table of connections; and the operator is applied to the situation that is to be changed. After the change has been made, a new situation has been created, which can be compared with the goal situation, and the process can then be repeated.

Consider, for example, a subject trying to solve one of the Moore-Anderson "recoding" problems. In this case, the problem is to change  $L1: r \cdot (\neg p \supset q)$  to  $L0: (q \vee p) \cdot r$ . The subject begins by saying, "You've got to change the places of the  $r$  to the other side and you have to change the . . . minus and horseshoe to wedge, and you've got to reverse the places from  $p$  and  $q$  to  $q$  and  $p$ , so let's see. . . . Rule 1 (i.e.,  $A \cdot B \rightarrow B \cdot A$ ) is similar to it because you want to change places with the second part. . . ."

The means-end chain in this example includes the following: notice the difference in order between the terms of  $L1$  and  $L0$ ; find an operator (rule 1) that changes the order.

Another kind of organization, which may be called *planning and abstraction*, is also evident in problem solving. In planning, some of the detail of the original problem is eliminated (abstracted). A solution is then sought for the simplified problem, using means-end analysis or other processes.

If the solution is found for the abstract problem, it provides an outline or plan for the solution of the original problem with the detail reinserted.

The programs for means-end analysis and for planning, each time they are activated, produce a "burst" of problem-solving activity directed at a particular subgoal or organization of subgoals. The problem-solving program also contains processes that control and organize these bursts of activity as parts of the total exploratory effort. [See PROBLEM SOLVING.]

**Rote memory processes.** The noticing processes incorporated in the problem-solving theory assume that humans have subprograms for discriminating among symbol structures (e.g., for noticing differences between structures) and programs for elaborating the fineness of these discriminations. They also assume that associations between symbol structures can be stored (e.g., the table of connections between differences and operators). Discrimination and association processes and the structures they employ constitute an important part of the detail of problem-solving activity but are obscured in complex human performances by the higher-level programs that organize and direct search.

In simpler human tasks—memorizing materials by rote—the organizing strategies are simpler, and the underlying processes account for most of the behavioral phenomena. It has been possible to provide a fairly simple information-processing explanation for the acquisition of discriminations and associations (Feigenbaum 1963). (Our description follows EPAM, the program for rote learning mentioned above.) In the learning situation, there develops in memory (a) a "sorting net," for discriminating among stimuli and among responses, and (b) compound symbol structures, stored in the net, that contain a partial representation, or "image," of the stimulus as one component and a partial image of the response as another.

When stimuli or responses are highly similar to each other, greater elaboration of the sorting net is required to discriminate among them, and more detail must be stored in the images. A stimulus becomes "familiar" as a result of repeated exposure and consequent elaboration of the sorting net and its stored image. We have already noted that these simple mechanisms have been shown to account, quantitatively as well as qualitatively, for some of the main features of learning rates that have been observed in the laboratory. [See LEARNING, article on DISCRIMINATION LEARNING.]

**Recognition of periodic patterns.** As an example of an information-processing explanation of

some of the phenomena of concept formation, we consider how, according to such a theory, human subjects detect and extrapolate periodic patterns—e.g., the letter pattern *A B M C D M . . .* (Simon & Newell 1964, pp. 293–294).

At the core of the explanation is the hypothesis that in performing these tasks humans make use of their ability to detect a small number of basic relations and operations: for example, the relations “same” and “different” between two symbols or symbol structures; the relation “next” on a familiar alphabet; and the operations of finding the difference between and the quotient of a pair of numbers. (These discriminations are not unlike those required as components in problem-solving programs to detect features of symbol structures and differences between them.) With a relatively simple program of these processes, the pattern in a sequence can be detected, the pattern can be described by a symbol structure, and the pattern description can be used by the interpretive process to extrapolate. In the example *A B M C D M*, the relation “next” is detected in the substring *A B C D*, and the relation “same” in the *M*’s. These relations are used to describe a three-letter pattern, whose next member is the “next” letter after *D*, i.e., *E*.

The information-processing theory of serial pattern detection has proved applicable to a wide range of cognitive tasks—including the Thurstone Letter Series Completion Test, symbol analogies tests, and partial reinforcement experiments. [See CONCEPT FORMATION; see also Feldman 1963.]

This article has described the use of simulation in constructing and testing theories of individual behavior, with particular reference to nonnumerical information-processing theories that take the form of computer programs. Examples of some of the current theories of problem solving, memorizing, and pattern recognition were described briefly, and the underlying assumptions about the information-processing characteristics of the central nervous system were outlined. Various techniques were illustrated for subjecting information-processing theories to empirical test.

## II

### ECONOMIC PROCESSES

Simulation is at once one of the most powerful and one of the most misapplied tools of modern economic analysis. “Simulation” of an economic system means the performance of experiments upon an analogue of the economic system and the drawing of inferences concerning the properties of the economic system from the behavior of its analogue. The analogue is an idealization of a generally more complex real system, the essential properties of which are retained in the analogue.

While this definition is consistent with the denotation of the word, the connotation of simulation among economists active in the field today is much more restricted. The term “simulation” has been generally reserved for processes using a physical

or mathematical analogue and requiring a modern high-speed digital or analogue computer for the execution of the experiments. In addition, most economic simulations have involved some stochastic elements, either as an intrinsic feature of the model or as part of the simulation experiment field. Thus, while a pencil-and-paper calculation on a two-person Walrasian economy would, according to the more general definition, constitute a simulation experiment, common usage of the term would require that, to qualify as a simulation, the size of the model must be large enough, or the relationships complex enough, to necessitate the use of a modern computing machine. Even the inclusion of probabilistic elements in the pencil-and-paper game would not suffice, in and of itself, to transform the calculations into a bona fide common-usage simulation. In order to avoid confusion, the term "simulation" will be used hereafter in its more restrictive sense.

To clarify the concept of simulation, it might be useful to indicate how the simulation process is related, on the one hand, to the analytic solution of mathematical models of an economy, and on the other, to the construction of mathematical and econometric models of economic systems.

The relationship between simulation and econometric and mathematical formulations of economic theories is quite intimate. It is these descriptions of economic processes that constitute the basic inputs into a simulation. After a mathematical or econometric model is translated into language a computing machine can understand, the behavior of the model, as described by the machine output, represents the behavior of the economic system being simulated. The solutions obtained by means of simulation techniques are quite specific. Given a particular set of initial conditions, a particular set of parameters, and the time period over which the model is to be simulated, a single simulation experiment yields a particular numerically specified set of time paths for the endogenous variables (the variables whose values are determined or explained by the model). A variation in one or more of the initial conditions or parameters requires a separate simulation experiment which provides a different set of time paths. Comparisons between the original solution and other solutions obtained under specific variations in assumptions can then be used to infer some of the properties of the relationships between input and output quantities in the system under investigation. In general, only very partial inferences concerning these relationships can be drawn by means of simulation experiments. In

addition, the results obtained can be assumed to be valid only for values of the parameters and initial conditions close to those used in the simulation experiments. By contrast, traditional mathematical approaches for studying the implications of an economic model produce general solutions by deductive methods. These general solutions describe, in functional form, the manner in which the model relates the endogenous variables to any set of initial conditions and parameters and to time.

The models formulated for a simulation experiment must, of course, represent a compromise between "realism" and tractability. Since modern computers enable very large numbers of computations to be performed rapidly, they permit the step-by-step solution of systems that are several orders of magnitude larger and more complicated than those that can be handled by the more conventional techniques. The representation of economic systems to be investigated with the aid of simulation techniques can therefore be much more complex; there are considerably fewer restrictions on the number of equations and on the mathematical forms of the functions that can be utilized. Simulation, therefore, permits greater realism in the extent and nature of the feed-back mechanisms in the stylized representation of the economy contained in the econometric or mathematical model.

The impetus for the use of simulation techniques in economics arises from three major sources. First, both theory and casual observation suggest that an adequate description of the dynamic behavior of an economy must involve complex patterns of time dependencies, nonlinearities, and intricate interrelationships among the many variables governing the evolution of economic activity through time. In addition, a realistic economic model will almost certainly require a high degree of disaggregation. Since analytic solutions can be obtained for only very special types of appreciably simplified economic models, simulation techniques, with their vastly greater capacity for complexity, permit the use of more realistic analogues to describe real economic systems.

The second driving force behind the use of simulation, one that is not unrelated to the first, arises from the need of social scientists in general and of economists in particular to find morally acceptable and scientifically adequate substitutes for the physical scientist's controlled experiments. To the extent that the analogue used in the simulation represents the relevant properties of the economic system under study, experimentation with the ana-

logue can be used to infer the results of analogous experiments with the real economy. The effects in the model of specific changes in the values of particular policy instruments (e.g., taxes, interest rates, price level) can be used to draw at least qualitatively valid inferences concerning the probable effects of analogous changes in the real economic system. Much theoretical analysis in economics is aimed at the study of the probable reactions of an economy to specified exogenous changes, but any economic model that can be studied by analytic techniques must of necessity omit so many obviously relevant considerations that little confidence can be placed in the practical value of the results. Since a simulation study can approximate the economy's behavior and structure considerably more closely, simulation experiments can, at least in principle, lead to conditional predictions of much greater operational significance.

Finally, the mathematical flexibility of simulation permits the use of this tool to gain insights into many phenomena whose intrinsic nature is not at all obvious. It is often possible, for example, to formulate a very detailed quantitative description of a particular process before its essential nature is sufficiently well understood to permit the degree of stylization required for a useful theoretical analysis. Studies of the sensitivity of the results to various changes in assumptions can then be used to disentangle the important from the unimportant features of the problem.

**Past uses of simulation.** The earliest applications of simulation approaches to economics employed physical analogues of a hydraulic or electrical variety. Analogue computers permit the solution of more or less complex linear or nonlinear dynamic systems in which time is treated as a continuous variable. They also enable a visual picture to be gained of adjustment processes. On the other hand, they are much slower than digital computers and can introduce distortions into the results because of physical effects, such as "noise" and friction, which have no conscious economic analogue.

Subsequent economic simulations have tended to rely primarily on digital computers. As the speed and memory capacity of the computers have improved, the economic systems simulated have become increasingly more complex and more elaborate, and the emphasis in simulation has shifted from use as a mathematical tool for solving systems of equations and understanding economic models to use as a device for forecasting and controlling real economies. In addition, these improvements in computer design have permitted the construction of microanalytic models in which ag-

gregate relationships are built up from specifications concerning the behavioral patterns of a large sample of microeconomic units.

As early as 1892, Irving Fisher recommended the use of hydraulic analogies "not only to obtain a clear and analytical picture of the interdependence of the many elements in the causation of prices, but also to employ the mechanism as an instrument of investigation and by it, study some complicated variations which could scarcely be successfully followed without its aid" (1892, p. 44). It was not until 1950, however, that the first hydraulic analogues of economic systems were constructed. Phillips (1950) used machines made of transparent plastic tanks and tubes through which colored water was pumped to depict the Keynesian mechanism of income determination and to indicate how the production, consumption, stocks, and prices of a commodity interact. Electrical analogues were used to study models of inventory determination (Strotz et al. 1957) and to study the business cycle models of Kalecki (Smith & Erdley 1952), Goodwin (Strotz et al. 1953), and others.

The shift to the use of digital computers began in the late 1950s. In a simulation study on an IBM 650, Adelman and Adelman (1959) investigated the dynamic properties of the Klein-Goldberger model of the U.S. economy by extrapolating the exogenous variables and solving the system of 25 nonlinear difference equations for a period of one hundred years. In this process no indications were found of oscillatory behavior in the model. The introduction of random disturbances of a reasonable order of magnitude, however, generated cycles that were remarkably similar to those characterizing the U.S. economy. On the basis of their study, they concluded that (1) the Klein-Goldberger equations may represent good approximations to the behavioral relationships in the real economy; and (2) their results are consistent with the hypothesis that the fluctuations experienced in modern highly developed societies are due to random perturbations.

Duesenberry, Eckstein, and Fromm (1960) constructed a 14-equation quarterly aggregative econometric model of the U.S. economy. Simulation experiments with this model were used to test the vulnerability of the U.S. economy to depressions and to assess the effectiveness of various automatic stabilizers, such as tax declines, increases in transfer payments, and changes in business savings.

A far more detailed and, indeed, the most ambitious macroeconometric simulation effort to date, at least on this side of the iron curtain, is being carried out at the Brookings Institution in Washington, D.C. The simulation is based on a 400-equation

tion quarterly econometric model of the U.S. economy constructed by various experts under the auspices of the Social Science Research Council (Duesenberry et al. 1965). The Brookings model has eight production sectors. For each of the non-government sectors there are equations describing the determinants of fixed investment intentions, fixed investment realizations, new orders, unfilled orders, inventory investment, production worker employment, nonproduction worker employment, production worker average weekly hours, labor compensation rates per hour, real depreciation, capital consumption allowances, indirect business taxes, rental income, interest income, prices, corporate profits, entrepreneurial income, dividends, retained earnings, and inventory valuation adjustment. The remaining expenditure components of the national product are estimated in 5 consumption equations, 11 equations for nonbusiness construction, and several import and export equations. For government, certain nondefense expenditures, especially at the state and local levels, are treated as endogenous variables, while the rest are taken as exogenous. On the income side of the accounts there is a vast array of additional equations for transfer payments, personal income taxes, and other minor items. The model also includes a demographic sector containing labor force, marriage rate, and household formation variables and a financial sector that analyzes the demand for money, the interest rate term structure, and other monetary variables. Finally, aside from a battery of identities, the model also incorporates two matrices: an input-output matrix that translates constant dollar GNP (gross national product) component demands into constant dollar gross product originating by industry, and a matrix that translates industry prices into implicit deflators for GNP components.

The solution to the system is achieved by making use of the model's block recursive structure. First, a block of variables wholly dependent on lagged endogenous variables is solved. Second, an initial simultaneous equation solution is obtained for variables in the "quantity" block (consumption, imports, industry outputs, etc.) using predetermined variables and using prices from the previous period in place of current prices. Third, a simultaneous equation solution is obtained for variables in the "price" block using the predetermined variables and the initial solution from the quantity block. Fourth, the price block solution is used as a new input to the quantity block, and the second and third steps are iterated until each variable changes (from iteration to iteration) by no more

than 0.1 per cent. Fifth, the three blocks are solved recursively.

Simulation experiments show that the system yields predictions both within and beyond the sample period that lie well within the range of accuracy of other models. Simulation studies have also been undertaken to determine the potential impact of personal-income and excise-tax reductions, of government expenditure increases, and of monetary tightness and ease. Stochastic simulations are also being carried out to ascertain the stability properties of the system.

A rather different approach to the estimation of behavioral relationships for the entire socioeconomic system has been developed by Orcutt and his associates (Orcutt et al. 1961). Starting with the observed behavior of microeconomic decision units rather than macroeconomic aggregates, they estimate behavioral relationships for classes of decision units and use these to predict the behavior of the entire system. For this purpose, functions known as operating characteristics are estimated from sample surveys and census data. These functions specify the probabilities of various outcomes, given the values of a set of status variables which indicate the relevant characteristics of the microeconomic units at the start of a period.

Their initial simulation experiments were aimed at forecasting demographic behavior. For example, to estimate the number of deaths occurring during a given month, the following procedure was applied: an operating characteristic,

$$\log P_i(m) = F_1[A_i(m - \frac{1}{2}), R_i, S_i] + (m - m_0)F_2[A_i(m - \frac{1}{2}), R_i, S_i] + F_3(m),$$

was specified. Here,  $P_i(m)$  indicates the probability of the death of individual  $i$  in month  $m$ ,  $A_i(m - \frac{1}{2})$  is the age of individual  $i$  at the start of month  $m$ ,  $R_i$  denotes the race of individual  $i$ , and  $S_i$  denotes the sex of individual  $i$ . The function  $F_1$  is a set of four age-specific mortality tables, one for each race and sex combination, which describe mortality conditions prevailing during the base month  $m_0$ . The function  $F_2$  is used to update each of these mortality tables to month  $m$ . The function  $F_3$  is a cyclic function which accounts for seasonal variations in death rates.

This and other operating characteristics were used in a simulation of the evolution of the U.S. population month by month between 1950 and 1960. A representative sample of the U.S. population consisting of approximately 10,000 individuals was constructed. In each month of the calculation a random drawing determined, in accordance with the probabilities specified by the relevant oper-

ating characteristics, whether each individual in the sample would die, marry, get divorced, or give birth. A regression analysis was then used to compare the actual and predicted demographic changes during the sample period. Close agreement was obtained. This approach is currently being extended to permit analysis of the consumption, saving, and borrowing patterns of U.S. families, the behavior of firms, banks, insurance companies, and labor unions, etc. When all portions of the microanalytic model have been fitted together, simulation runs will be made to explore the consequences of various changes in monetary and fiscal policies.

So far, we have discussed simulation experiments for prediction purposes only. However, the potential of simulation as an aid to policy formulation has not been overlooked by development planners in either free-enterprise economies or socialist countries. A microanalytic simulation model has been formulated at the U.S.S.R. Academy of Sciences in order to guide the management of the production system of the Soviet economy (Cherniak 1963). The model is quite detailed and elaborate. It starts with individual plants at a specific location and ends up with interregional and interindustry tables for the Soviet Union as a whole. In addition, the U.S.S.R. is contemplating the introduction of a 10-step joint man-computer program. The program is to be cyclic, with odd steps being man-operated and even steps being computer-operated. The functions fulfilled by the man-operated steps include the elaboration of the initial basis of the plan, the establishment of the criteria and constraints of the plan, and the evaluation of results. The computer, on the other hand, will perform such tasks as summarizing and balancing the plan, determining optimal solutions to individual models, and simulating the results of planning decisions. This procedure will be tested at a level of aggregation corresponding to an industrial sector of an economic council and will ultimately be extended to the economy as a whole. I have been unable to find any information on the progress of this work more recent than that in Cherniak (1963).

To take an example from the nonsocialist countries, a large-scale interdisciplinary simulation effort was undertaken at Harvard University, at the request of President John F. Kennedy, in order to study the engineering and economic development of a river basin in Pakistan. The major recommendations of the report (White House 1964) are currently being implemented by the Pakistani government, with funds supplied by the U.S. Agency for International Development.

In Venezuela a 250-equation dynamic simulation model has been constructed by Holland, in conjunction with the Venezuelan Planning Agency and the University of Venezuela. This model, which is based on experience gained in an earlier simulation of a stylized underdeveloped economy (Holland & Gillespie 1963), is being used in Venezuela to compare, by means of sensitivity studies, the repercussions of alternative government expenditure programs on government revenues and on induced imports, as well as to check the consistency of the projected rate of growth with the rate of investment and the rate of savings. An interesting macroeconomic simulation of the Ecuadorian economy, in which the society has been disaggregated into four social classes, is currently being carried out by Shubik (1966).

*Monte Carlo studies.* The small sample properties of certain statistical estimators cannot be determined using currently available mathematical analysis alone. In such cases simulation methods are extremely useful. By simulating an economic structure (including stochastic elements) whose parameters are known, one generates samples of "observations" of a given sample size. Each sample is then used to estimate the parameters by several estimation methods. For each method, the distribution of the estimates is compared with the true values of the parameters to determine the properties of the estimator for the given sample size. This approach, known as the Monte Carlo sampling method, has frequently been applied by econometricians in studies of the small sample properties of alternative estimators of simultaneous equation models [see SIMULTANEOUS EQUATION ESTIMATION].

*Limitations and potential.* To a large extent, the very strength of simulation is also its major weakness. As pointed out earlier, any simulation experiment produces no more than a specific numerical case history of the system whose properties are to be investigated. To understand the manner of operation of the system and to disentangle the important effects from the unimportant ones, simulation with different initial conditions and parameters must be undertaken. The results of these sensitivity studies must then be analyzed by the investigator and generalized appropriately. However, if the system is very complex, these tasks may be very difficult indeed. To enable interpretation of results, it is crucial to keep the structure of the simulation model simple and to recognize that, as pointed out in the definition, simulation by no means implies a blind imitation of the actual situation. The simulation model should express

only the logic of the simulated system together with the elements needed for a fruitful synthesis.

Another major problem in the use of simulation is the interaction between theory construction and simulation experiments. In many cases simulation has been used as an alternative to analysis, rather than as a supplementary tool for enriching the realm of what can be investigated by other, more conventional techniques. The inclination to compute rather than think tends to permeate a large number of simulation experiments, in which the investigators tend to be drowned in a mass of output data whose general implications they are unable to analyze. There are, of course, notable exceptions to this phenomenon. In the water-resource project (Dorfman 1964), for example, crude analytic solutions to simplified formulations of a given problem were used to pinpoint the neighborhoods of the solution space in which sensitivity studies to variations in initial conditions and parameters should be undertaken in the more complex over-all system. In another instance, insights gained from a set of simulation experiments were used to formulate theorems which, once the investigator's intuition had been educated by means of the simulation, were proved analytically. Examples of such constructive uses of simulation are unfortunately all too few.

Finally, in many practical applications of simulation to policy and prediction problems, insufficient attention is paid to the correspondence between the system simulated and its analogue. As long as the description incorporated in the simulation model appears to be realistic, the equivalence between the real system and its analogue is often taken for granted, and inferences are drawn from the simulation that supposedly apply to the real economy. Clearly, however, the quality of the input data, the correspondence between the behavior of the outputs of the simulation and the behavior of the analogous variables in the real system, and the sensitivity of results to various features of the stylization should all be investigated before inferences concerning the real world are drawn from simulation experiments.

In summary, simulation techniques have a tremendous potential for both theoretical analysis and policy-oriented investigations. If a model is chosen that constitutes a reasonable representation of the economic interactions of the real world and that is sufficiently simple in its structure to permit intelligent interpretation of the results at the present state of the art, the simulations can be used to acquire a basic understanding of, and a qualitative feeling for, the reactions of a real economy to vari-

ous types of stimuli. The usefulness of the technique will depend crucially, however, upon the validity of the representation of the system to be simulated and upon the quality of the compromise between realism and tractability. Presumably, as the capabilities of both high-speed computers and economists improve, the limitations of simulation will be decreased, and its usefulness for more and more complex problems will be increased.

### III POLITICAL PROCESSES

A political game or political simulation is a type of model that represents some aspect of politics. The referent, or "reality," represented by a simulation, may be technique may be some existing, past, or hypothetical system or process. Regardless of the reference system or process depicted in a game or simulation, the model is always a simplified version of the total process. Some political features will be excluded. Those elements of political phenomena represented by the model are reduced in complexity. The model's structure and selected input produce a representation of the process, as well as the nature of possible decisions. These latter elements of models are also applicable to other kinds of models, whether they be natural, physical, or mathematical.

Simulations and games differ from other types of models in that their interested elements are limited to measuring different values as the system or process operates or evolves. In other words, the model does not transform some of the elements of the model. For example, a game model is designed to show the effect of a particular human decision in a game, but there are restrictions to make the game resemble the other rules. Instead of some game, a political game is a model that is designed to show the effect of a particular human decision in a political process. In the case of a political game, the model is designed to show the effect of a particular human decision in a political process.

also occur in the relationships between the players. When the value of one element in the model is changed, related properties can be adjusted accordingly. Because of this ability to handle change and change, Brody has described simulations and games as "operating models" (1963, p. 670).

Games versus simulations. To the users of both techniques, the distinctions between games and simulations are still ambiguous, as some current definitions will illustrate.

Brody (1963) and Guetzkow and his associates (1963) distinguish between (1) machine, or computer, simulations, (2) man, or manual, games, and (3) mixed, or man-computer, simulations. Generally the "machine" referred to is a digital computer, although some simulations involve other types of calculating equipment. The extension of the term "simulation" to cover those models which are a mixture of man and machine does not occur in other definitions. For example, the concept "simulation" is confined by Pool, Abelson, and Fagan (1965) to models that are completely operated by a computer. Rapoport (1964) defines a simulation as a technique in which both the assessment of the situation and the subsequent decisions are made in accordance with explicit and formal rules. When either assessment or decisions are made by human beings without formal rules, the technique is described as a game. When both assessment and decision are made by men, Rapoport stipulates that the device is a scenario. A different interpretation is given by Shubik, who suggests that a game "is invariably concerned with studying human behavior or teaching individuals" (1964, p. 71). On the other hand, a simulation is designated as the representation of a human or human system in which the actual presence of human is not essential because their behavior is part of the game of the simulated environment. The necessary involvement of human in games was apparent in the definitions of Thorrell and Graves (1964) and Dawson (1962). In Dawson's classification all operating models are simulations, but only those which introduce human players are games.

In these definitions of games and simulations, two distinguishing criteria are necessary. The distinctions are differentiated either by the role assigned to human participants or by the role assigned to formal rules of change or transformation. When human participation is the distinguishing feature, a game is described as an operating model in which participants are present and a simulation is a model without players. With rules of transformation as the criterion, the type of model without human

**Domestic and CIAPOM simulations.** The dynamics of them are created by a combination of program activity and quantitative data. In summary, the operations of the international government simulation in January 1966, 1 are computer programmed on a computer. Nine major factors and nine streams enter to contemporary world politics are discussed in the program. To keep it relatively realistic the operator supplies the distribution of the nine major nations along two dimensions: an approximate relative membership (weight factor, trade, and geographical location) from 1966 data; inputs the computer generates the matrix of the international system. In course of each round a matrix is created areas, and other international factors.

The operator then determines as action by one of the major nations against one of the several other nations (as determined by one of the degree of national effort required— from dependent position to self aid). From this information, the computer program determines the proposed cost of the other nations. The effects of the action action and resulting counteractions are then computed for each round (and the international system). With these two parameters the operator may specify another action.

In more more complex computer simulation of international relations, TIMPIL (Technological, Military, and Political) Simulation from 1966 is currently being developed for the Joint War Game Agency of the U.S. Army, Chief of Staff (1966). Based on TIMPIL is the international system political, economic, cultural, and military factors of 45 nations in 20 matrix which are derived from 11 "variables included in the program."

**Comments.** Whereas the Domestic simulation and TIMPIL are computer representations of international systems, *Comments* Paul & Kasser have reported the psychological difficulties in the field which affect their laboratory processing. In the course from the future system representation, it is necessary deal with through policy, and the simulation inputs are messages that present the interaction between international system. The policy factors and the material three factor, however might be adapted for other level of political interaction.

The messages that from the computer are assessed for affect, attitude or feeling of one nation toward another, and national (like responses) directed to the other in response. Each message is given different, or made to depend on the conditions. Domestic system simulation, or programmatic system, that reflect psychological interactions about

the relations and formation of international. For example, some situation is given a message that long war increases pressure international. The timing of international interaction when action are selected by the policy makers for domestic and domestic. The timing program the only interaction the process is in the course of action that are given more about the domestic factor, affect factor. The affect stream represents the future course a perception of how each nation feels toward all the other nations in the world in a way of Comments the action and the war more domestic, but more given about the timing when action is the next phase in the beginning of World War 1. At the end of the simulation work, the differences in the affect measures, and the events by which there were varying national responses differences between the actual historical figures.

**Accelerating election simulation.** The National Election Commission has applied an all-computer simulation in the 1966 and 1968 American presidential elections (1966 to all 1968). The simulation is represented in the computer in the form of units. Every unit was is specified by a number, one of them that reflect geographical region, the size, etc. each geographical cluster political party, and output. The each unit system information is stored in the political characteristics, the example countries is one, part-time, money, and output in various political events. The computer list for the "multi-layers" are based from various system, political, cultural, history, and output (1966). The assumption of various could possible in the course of political activities in the United States, provide a more detailed representation of various that is obtained in any single political factor the simulation can be applied in a particular election, the operators must decide what characteristics and factors are used before. Represented in more of transformation are written to express the impact of the system in different kinds of units.

In the 1966 campaign, a program which contains a political representation procedure in the future election, and given about the government, more something in the course of the election work. The simulation modeling of the system contained, all with the actual results was in 1966, the operators introduced into the computer program, primarily represented the effects of these "transformations" and input, nuclear transformation, and more well face. This time the percentage of the unit in each state directed by history was generated, and the influence with the game system was on.

**Other operating models.** The benefits of the political system simulation national governments and

procedures but do not form an exhaustive list of those techniques currently used in political inquiry. For example, the Simulmatics project is not the only computer simulation of political elections. McPhee (1961), Coleman (1965), and Abelson and Bernstein (1963) have constructed simulations representing not only the election outcome but also the process by which voters form opinions during the campaign. The last model differs from the others by representing a local community referendum.

Other games and simulations range from local politics games (Wood 1964) to games of international balance of power (Kaplan et al. 1960); from simulations of disarmament inspection (Singer & Hinomoto 1965) to those of a developing nation (Scott & Lucas 1966). In addition, other operating models not directly concerned with the study of political phenomena are relevant. Abstract games of logic developed by Layman Allen are used in the study of judicial processes at the Yale Law School. Bargaining games, such as those advanced by Thomas Schelling (1961), and the substantial number of business and management simulations (K. Cohen et al. 1964; American Management Association 1961; Thorelli & Graves 1964) have political applications, as do some of the numerous war games (Giffin 1965).

### Uses of political gaming and simulation

The development and operation of a game or simulation demand time, effort, and finances. Moreover, operating models are beset by such difficulties as the question of their political validity. Despite these problems, games and simulations have been considered to be useful techniques in research, instruction, and policy formation.

**Research.** Many of the research attractions of operating models can be summarized in their ability to permit controlled experimentation in politics. In political reality, determination of the effects of a phenomenon can be severely hindered by confounding influences of potentially related events. Through a carefully designed model, an experimenter can isolate a property and its effects by either deleting the competing mechanisms from the model or holding them constant. Not only can a game or simulation be manipulated, but it can also be subjected to situations without the permanent and possibly harmful consequences that a comparable event might create in the real world.

This ability of the researcher to control the model permits replications and increased access. To establish a generalized pattern, repeated obser-

vations are required. A simulation or game can be assigned the same set of initial conditions and played over and over again, whereas in its reference system the natural occurrence of a situation might appear infrequently and perhaps only once. Moreover, replications of an operating model may reveal a greater range of alternative responses to a situation than could otherwise be identified.

Increased access to the objects of their research also leads students of politics to consider operating models. Players in a political game can be continuously observed; a detailed set of their written and verbal communications can be secured; and they can be asked to respond to interviews, questionnaires, or other test instruments at points selected by the researcher. Computer simulations can be instructed to provide a "print-out" at any specified stage of their operation, thus providing a record for analysis. The diversity of means by which data are readily obtained from such models contrasts with the limited access to the crowded lives of actual policy makers and their often sensitive written materials.

In addition to control, replication, and access, gaming and simulation contribute in at least two ways to theory building. First, the construction of a game or a simulation requires the developer to be explicit about the units and relationships that are to exist in his model and presumably in the political reference system it represents. An essential component of the political process which has been ignored in the design of a game is dramatized for the discerning observer. A computer simulation necessitates even more explication of the relationships among the model's components. An incomplete program may terminate abruptly or result in unintelligible output. Thus, in constructing an operating model a relationship between previously unconnected findings may be discovered. Alternatively, a specific gap in knowledge about a political process may be pinpointed, and hypotheses, required by the model, may be advanced to provide an explanation.

A second value for theory building results from the operating, or dynamic, quality of games and simulations. Static statements of relationships can be transformed into processes which respond to change without the restrictions imposed by such alternatives as linear regression models. According to Abelson and Bernstein (1963, p. 94), "... the static character of statistical models and their reliance on linear assumptions seem to place an upper limit on their potential usefulness. . . . Computer simulation offers a technique for formulating

systemic models, thus promising to meet this need."

It should be recognized that these research assets are not shared equally by all political games and simulations. For example, a computer simulation may not generate the range of potential alternatives to a situation provided by a series of games played with policy experts. On the other hand, control and replication are more easily achieved in a programmed computer simulation than in a political game in which players are given considerable latitude in forming their own patterns of interaction.

**Instruction.** Simulations involving human participants and games are being used in graduate and undergraduate instruction as well as in secondary school teaching. Several evaluations of these techniques for college and university teaching have been reported in political science (e.g., Alger 1963; Cohen 1962) and in other fields (e.g., Thorelli & Graves 1964, especially pp. 25-31; Conference on Business Games 1963). One of these reports (Alger 1963, pp. 185-186) summarizes the frequently cited values of a simulation or game as a teaching aid: "(1) It increases student interest and motivation; (2) It serves as a laboratory for student application and testing of knowledge; (3) It provides insight into the decision-maker's predicament; (4) It offers a miniature but rich model that facilitates comprehension of world realities."

In contrast to the positive evaluations of users like Alger, a critical assessment of the instructional merits of political gaming and simulation has been offered by Cohen (1962). On the basis of a game he conducted, Cohen questioned (1) whether the game increased motivation among students not already challenged by the course; (2) whether the game stimulated interest in more than a narrow segment of the entire subject matter; (3) whether the game misrepresented or neglected critical features of political reality, thereby distorting the image of political phenomena; and (4) whether a comparable investment by both instructor and students in more conventional modes of learning might have offered a larger increment in education.

Systematic educational research has yet to clarify the differing evaluations of games and simulations for instruction. In one educational experiment with a political simulation (Robinson et al. 1966), undergraduate students in each of three courses were divided into two groups controlled for intelligence, grade-point average, and certain personality characteristics. One group augmented its

regular course activities by a weekly discussion of relevant case studies. The other group in each course participated in a continuing simulation for an equal amount of time. Although most measures of student interest did not indicate significant differences between the groups, students evinced more interest in the case studies, while attendance was higher in the simulation group. Similarly, no direct and unmediated difference was found between the two groups on either mastery of facts or principles. To date, the limited educational research on gaming in other fields (e.g., Conference on Business Games 1963) also has produced ambiguous results.

It may be that the more knowledge students have in the subject area of a model or game, the more complex and detailed it must be to provide a satisfactory learning experience. One instructional use of games and simulations that may prove particularly useful with sophisticated students is to involve them in the construction of a model rather than to simply have them assume the role of players.

**Policy formation.** In some respects the application of games and simulations as adjuncts to policy formation is only an extension of their use for research and instruction. Policy makers have employed games or man-machine simulations as training aids for governmental officials in the same manner as management-training programs have incorporated business games. In the Center for International Studies game at the Massachusetts Institute of Technology, "questionnaires returned by participants have revealed that responsible officials . . . place a uniformly high value on the special benefits the games provide, particularly in sharpening their perspectives of alternatives that could arise in crisis situations" (Bloomfield & Whaley 1965, p. 866).

Simulation and gaming research performed under government contract or with more or less direct policy implications has concerned such issues as the systemic consequences of the proliferation of nuclear weapons (Brody 1963), the impact on political decision making of situational characteristics associated with crisis (Hermann 1965), and the potential role of an international police force at various stages of disarmament (Bloomfield & Whaley 1965). An application of simulation research for political campaigns is reflected in the election simulations conducted under contract to the National Committee of the Democratic Party by the Simulmatics Corporation (Pool et al. 1965). One of the major areas of U.S. government-related

activity involving operating models is war gaming and its extension to cover relevant political aspects of national security. Public material on these activities, however, is limited.

### Validity—evaluating correspondence

How are the elements of political reality estimated in a way to make their transmission to an operating model accurate? What are the implications of representing political properties by deterministic or stochastic processes? What are the relative advantages of games compared to simulations? If humans act as participants, how can the motivations of actual political leaders be reproduced? Underlying most of these questions is the problem of validity. Operating models are by definition representations of an existing or potential system or process. They are constructed for the information they can provide about a selected reference system. If in comparison to the performance of the reference system the simulation or game produces spurious results, the model is of little worth. An estimation of the "goodness of fit" or extent of similarity between an operating model and external criteria is, therefore, the central problem of validity.

Different types of criteria or standards can be used for evaluating the correspondence between operating models and their reference system (Hermann 1967). To date, however, the only effort at validity that has been applied to most simulations and games uses no specific criterion of comparison. In this approach, called face validity, the model's realism is based on impressionistic judgments of observers or participants. If participants are used, face validity may concern estimates of their motivation or involvement. Unfortunately, participants can be motivated in a game that incorrectly represents the designated political environment. Furthermore, if the operating model involves the substitution of one property for another, some feature may give the appearance of being quite unreal even though it replicates the performance of the real-world property it replaces.

When specific criteria for correspondence are established, model validity may be determined by comparing events, variables and parameters, or hypotheses. In the first case, the product or outcome of the operating model is compared to the actual events it was intended to replicate (e.g., the correlation between the state-by-state election returns in the 1960 U.S. presidential campaign and those projected by the Simulmatics Corporation's model; Pool et al. 1965). The second approach compares the variables and parameters that consti-

tute a model with the real-world properties they are intended to represent (e.g., a current study uses factor analysis of the core variables of a simulation and the quantifiable real-world indices for which the simulation variables have been substituted; validity judgments are made from comparisons of the factors and of the variables that load on each factor; see Chadwick 1966). The third approach to validity compares the statistical results of a number of hypotheses tested in an operating model with comparable tests of the same hypotheses conducted with data drawn from the reference system (e.g., Zinnes 1966). Confirmation of a variety of hypotheses in both the operating model and in the actual political system increases confidence in the model's validity.

With the exception of face validity, each of the described validity approaches requires that values for specified properties be determined with precision for both the operating model and its reference system. Not only is this procedure often difficult, but in some instances it may not be appropriate. Imagine a political game designed as an aid for policy making whose purpose is to display as many different alternative outcomes to an initial situation as possible. The fact that the subsequent course of actual events leads to only one of those outcomes—or perhaps, none of them—may not reduce the utility of the exercise for increasing the number of alternatives considered by the policy makers. In other instances, an operating model may be consistent with one of the described validity criteria but remain unsatisfactory for some purposes. One illustration is an election simulation in which the winning political party is decided by a stochastic process. With correct probability settings and frequent elections in the model, the simulation's distribution of party victories would closely approximate election outcomes in the reference system. Despite the apparent event validity, the simulation would be undesirable for instruction in election politics. The naive participant might conclude from his experience with the collapsed campaign process that party victory is determined exclusively by chance.

In summary, a variety of validity strategies exist. The appropriate strategy varies from model to model and with the purpose for which the game or simulation was designed. Each operating model must be independently validated. At any given time the confidence in the accuracy with which a game or simulation represents its intended political reference system will be a matter of degree. Evaluation of these operating models for the study of

politics will depend upon the development and application of procedures for measuring the extent to which each model's purposes are fulfilled.

#### SIMULTANEOUS EQUATION ESTIMATION

The distinction between partial and general equilibrium analysis in economic theory is well grounded [see ECONOMIC EQUILIBRIUM]. Early work in econometrics paid inadequate attention to this distinction and overlooked for many years the possibilities of

improving statistical estimates of individual economic relationships by embedding them in models of the economy as a whole [see *ECONOMETRIC MODELS, AGGREGATE*]. The earliest studies in econometrics were concerned with estimating parameters of demand functions, supply functions, production functions, cost functions, and similar tools of economic analysis. The principal statistical procedure used was to estimate the  $\alpha$ 's in the relation

$$y_t = \sum_{i=1}^n \alpha_i x_{it} + u_t, \quad t = 1, 2, \dots, T,$$

using the criterion that  $\sum_{t=1}^T u_t^2$  be minimized. This is the principle of "least squares" applied to a single equation in which  $y_t$  is chosen as the dependent variable and  $x_{1t}, \dots, x_{nt}$  are chosen as the independent variables. The criterion is the minimization of the sum of squared "disturbances" ( $u_t$ ) which are assumed to be unobserved random errors. The estimation of the unknown parameters  $\alpha_i$  is based on the sample of  $T$  observations of  $y_t$  and  $x_{1t}, \dots, x_{nt}$ . This is the usual statistical model and estimation procedure that is used in controlled experimental situations where the set of independent variables consists of selected, fixed variates for the experimental readings on  $y_t$ , the dependent variable. [See *LINEAR HYPOTHESES, article on REGRESSION*.]

However, economics, like most other social sciences, is largely a nonexperimental science, and it is generally not possible to control the values of  $x_{1t}, \dots, x_{nt}$ . The values of the independent variables, like those of the dependent variable, are produced from the general outcome of economic life, and the econometrician is faced with the problem of making statistical inferences from nonexperimental data. This is the basic reason for the use of simultaneous equation methods of estimation in econometrics. In some situations  $x_{1t}, \dots, x_{nt}$  may not be controlled variates, but they may have a one-way causal influence on  $y_t$ . The main point is that least squares yields desirable results only if  $u_t$  is independent of  $x_{1t}, \dots, x_{nt}$ , that is, if  $E(u_t x_{it}) = 0$  for all  $i$  and  $t$ .

**Properties of estimators.** If the  $x_{it}$  are fixed variates, estimators of  $\alpha_i$  obtained by minimizing  $\sum u_t^2$  are *best linear unbiased* estimators. They are linear estimators because, as shown below, they are linear functions of  $y_t$ . An estimator,  $\hat{\alpha}_i$ , of  $\alpha_i$  is called unbiased if

$$E\hat{\alpha}_i = \alpha_i,$$

i.e., if the expected value of the estimator equals the true value. An estimator is best if among all unbiased estimators it has the least variance, i.e., if

$$E(\hat{\alpha}_i - \alpha_i)^2 \leq E(\tilde{\alpha}_i - \alpha_i)^2,$$

where  $\tilde{\alpha}_i$  is any other unbiased estimator. Clearly, the properties of being unbiased and best are desirable ones. These properties are defined without reference to sample size. Two related but weaker properties, which are defined for large samples, are *consistency* and *efficiency*.

An estimator,  $\hat{\alpha}_i$ , is consistent if  $\text{plim } \hat{\alpha}_i = \alpha_i$ , that is, if

$$\lim_{T \rightarrow \infty} P(|\hat{\alpha}_i - \alpha_i| < \epsilon) = 1, \quad \text{for any } \epsilon > 0.$$

This states that the probability that  $\hat{\alpha}_i$  deviates from  $\alpha_i$  by an amount less than any arbitrarily small  $\epsilon$  tends to unity as the sample size  $T$  tends to infinity.

Consider now the class of all consistent estimators that are normally distributed as  $T \rightarrow \infty$ . An *efficient* estimator of  $\alpha_i$  is a consistent estimator whose asymptotic normal distribution has a smaller variance than any other member of this class. [See *ESTIMATION*.]

**Inconsistency of least squares.** The choice of estimators,  $\hat{\alpha}_i$ , such that  $\sum_{t=1}^T (y_t - \sum_{i=1}^n \alpha_i x_{it})^2$  is minimized is formally equivalent to the empirical implementation of the condition that  $E(u_t x_{it}) = 0$ , since the first-order condition for a minimum is

$$\sum_{t=1}^T [(y_t - \sum_{i=1}^n \alpha_i x_{it}) x_{it}] = 0.$$

On the one hand, the  $\alpha_i$  are estimated so as to minimize the residual sum of squares. On the other hand, they are estimated so that the residuals are uncorrelated with  $x_{1t}, \dots, x_{nt}$ . The possible inconsistency of this method is clearly revealed by the latter criterion, for if it is assumed that the  $u_t$  are independent of  $x_{1t}, \dots, x_{nt}$  when they actually are not, the estimators will be inconsistent. This is shown by the formula

$$\text{plim } \hat{\alpha}_i = \alpha_i + \text{plim } \frac{1}{|\mathbf{M}|} \sum_{j=1}^n m_{uj} \mathbf{M}_{ji},$$

where  $\mathbf{M}$  is the moment matrix whose typical element is  $\sum_t x_{it} x_{jt}$ ;  $|\mathbf{M}|$  is the determinant of  $\mathbf{M}$ ;  $m_{uj}$  is  $\sum_t u_t x_{jt}$ ; and  $\mathbf{M}_{ji}$  is the  $j, i$  cofactor of  $\mathbf{M}$ . The inconsistency in the estimator is due to the nonvanishing probability limit of  $m_{uj}$ . In a nonexperimental sample of data, such as that observed as the joint outcome of the uncontrolled simultaneous economic process, we would expect many or all the  $x_{it}$  in a problem to be dependent on  $u_t$ .

**Identifying restrictions.** Since economic models consist of a set of simultaneous equations generating nonexperimental data, the equations of the model must be *identified* prior to statistical estimation. Unless some restrictions are imposed on

specific relationships in a linear system of simultaneous equations, every equation may look alike to the statistician faced with the job of estimating the unknown coefficients. The economist must place a priori restrictions, in advance of statistical estimation, on each of the equations in order to identify them. These restrictions may specify that certain coefficients are known in advance—especially that they are zero, for this is equivalent to excluding the associated variable from an economic relation. Other restrictions may specify linear relationships between the different coefficients.

Consider the generalization of a single equation,

$$y_t = \sum_{i=1}^m \alpha_i z_{it} + u_{it},$$

where  $E(z_{it}u_{it}) = 0$  for all  $i$  and  $t$ , to a whole system,

$$\sum_{j=1}^m \beta_{ij} y_{jt} + \sum_{k=1}^m \gamma_{ik} z_{kt} = u_{it}, \quad i = 1, 2, \dots, n,$$

where  $E(z_{kt}u_{it}) = 0$  for all  $k, i$ , and  $t$ . Every variable enters every equation linearly without restriction, and the statistician has no way of distinguishing one relation from another. Zero restrictions, if imposed, would have the form  $\beta_{rs} = 0$  or  $\gamma_{pq} = 0$ , for some  $r, s, p$ , or  $q$ . In many equations, we may be interested in specifying that sums or differences of variables are economically relevant combinations, i.e., that  $\beta_{rs} = \beta_{ru}$  or that  $\beta_{rs} = -\gamma_{rw}$  or, more generally, that

$$\sum_{s=1}^{m_r} w_{rs} \beta_{rs} + \sum_{s=1}^{m_r} v_{rs} \gamma_{rs} = 0.$$

The last restriction implies that a homogeneous linear combination of parameters in the  $r$ th equation is specified to hold on a priori grounds. The weights  $w_s$  and  $v_s$  are known in advance.

If general linear restrictions are imposed on the equations of a linear system, we may state the following rule: an equation in a linear system is identified if it is not possible to reproduce by linear combination of some or all of the equations in the system an equation having the same statistical form as the equation being estimated.

If the restrictions are of the zero type, a necessary condition for identification of an equation in a linear system of  $n$  equations is that the number of variables excluded from that equation be greater than or equal to  $n - 1$ . A necessary and sufficient condition is that it is possible to form at least one nonvanishing determinant of order  $n - 1$  out of those coefficients, properly arranged, with which the excluded variables appear in the  $n - 1$  other equations (Koopmans et al. 1950).

Criteria for identifiability are stated here for

linear equation systems. A more general treatment in nonlinear systems is given by Fisher (1966). [See STATISTICAL IDENTIFIABILITY.]

### Alternative estimation methods

Assuming that we are dealing with an identified system, let us turn to the problems of estimation. In the system of equations above, the  $y_{jt}$  are *endogenous* or *dependent* variables and are equal in number to the number of equations in the system,  $n$ . The  $z_{kt}$  are *exogenous* variables and are assumed to be *independent* of the disturbances,  $u_{it}$ .

In one of the basic early papers in simultaneous equation estimation (Mann & Wald 1943), it was shown that large-sample theory would, under fairly general conditions, permit lagged values of endogenous variables to be treated like purely exogenous variables as far as consistency in estimation is concerned. Exogenous and lagged endogenous variables are called *predetermined* variables.

Early econometric studies, for example, that of Tinbergen (1939), were concerned with the estimation of a number of individual relationships in which the possible dependence between variables and disturbances was ignored. These studies stimulated Haavelmo (1943) to analyze the consistency problem, for he noted that the Tinbergen model contained many single-equation least squares estimates of equations that were interrelated in the system Tinbergen was constructing, which was intended to be a theoretical framework describing the economy that generated the observations used.

The lack of independence between disturbances and variables can readily be demonstrated. Consider the two-equation system

$$\beta_{11}y_{1t} + \beta_{12}y_{2t} + \sum_{k=1}^m \gamma_{1k}z_{kt} = u_{1t}$$

$$\beta_{21}y_{1t} + \beta_{22}y_{2t} + \sum_{k=1}^m \gamma_{2k}z_{kt} = u_{2t}.$$

The  $z_{kt}$  are by assumption independent of  $u_{1t}$  and  $u_{2t}$ . Some of the  $\gamma$ 's are specified to be zero or are otherwise restricted so that the two equations are identified. Suppose we wish to estimate the first equation. To apply least squares to this equation, we would have to select either  $y_1$  or  $y_2$  as the dependent variable. Suppose we select  $y_1$  and set  $\beta_{11}$  equal to unity. We would then compute the least squares regression of  $y_1$  on  $y_2$  and the  $z_k$  according to the relation

$$y_{1t} = -\beta_{12}y_{2t} - \sum_{k=1}^m \gamma_{1k}z_{kt} + u_{1t},$$

which incorporates all the identifying restrictions on the  $\gamma$ 's.

For this procedure to yield consistent estimators,  $y_{2t}$  must be independent of  $u_{1t}$ . The question is whether the existence of the second equation has any bearing on the independence of  $y_{2t}$  and  $u_{1t}$ . Multiplying the second equation by  $u_{1t}$  and forming expectations, we have

$$E(y_{2t}u_{1t}) = -(\beta_{21}/\beta_{22})E(y_{1t}u_{1t}) + (1/\beta_{22})E(u_{1t}u_{2t}).$$

From the first equation (with  $\beta_{11} = 1$ ), we have

$$E(y_{1t}u_{1t}) = -\beta_{12}E(y_{2t}u_{1t}) + E(u_{1t}^2).$$

Combining these two expressions, we obtain

$$E(y_{2t}u_{1t}) = \frac{E(u_{1t}u_{2t}) - \beta_{12}E(u_{1t}^2)}{\beta_{22} - \beta_{12}\beta_{21}}.$$

In general, this expression does not vanish, and we find that  $y_{2t}$  and  $u_{1t}$  are not independent.

**The maximum likelihood method.** The maximum likelihood method plays a normative role in the estimation of economic relationships, much like that played by perfect competition in economic theory. This method provides consistent and efficient estimators under fairly general conditions. It rests on specific assumptions, and it may be hard to realize all these assumptions in practice or, indeed, to make all the difficult calculations required for solution of the estimation equations.

For the single-equation model, the maximum likelihood method is immediately seen to be equivalent to ordinary least squares estimation for normally distributed disturbances. Let us suppose that  $u_1, \dots, u_T$  are  $T$  independent, normally distributed variables. The  $T$ -element sample has the probability density function

$$p(u_1, \dots, u_T) = \left( \frac{1}{\sqrt{2\pi}\sigma} \right)^T \exp \left( -\frac{1}{2\sigma^2} \sum_{t=1}^T u_t^2 \right).$$

By substitution we can transform this joint density of  $u_1, \dots, u_T$  into a joint density of  $y_1, \dots, y_T$ , given  $x_{11}, \dots, x_{n1}, x_{12}, \dots, x_{n2}, \dots, x_{nT}$ , namely,

$$p(y_1, \dots, y_T | x_{11}, \dots, x_{nT}) = \left( \frac{1}{\sqrt{2\pi}\sigma} \right)^T \exp \left[ -\frac{1}{2\sigma^2} \sum_{t=1}^T \left( y_t - \sum_{i=1}^n \alpha_i x_{it} \right)^2 \right].$$

This function will be denoted as  $L$ , the likelihood function of the sample, and is seen to depend on the unknown parameters  $\alpha_1, \dots, \alpha_n$  and  $\sigma$ . We maximize this function by imposing the following conditions:

$$\frac{\partial \log L}{\partial \alpha_i} = -\frac{1}{\sigma^2} \sum_{t=1}^T \left[ \left( y_t - \sum_{j=1}^n \alpha_j x_{jt} \right) x_{it} \right] = 0, \quad i = 1, \dots, n,$$

$$\frac{\partial \log L}{\partial \sigma} = -\frac{T}{\sigma} + \frac{1}{\sigma^3} \sum_{t=1}^T \left( y_t - \sum_{j=1}^n \alpha_j x_{jt} \right)^2 = 0.$$

These are recognized as the "normal" equations of single-equation least squares theory and the estimation equation for the residual variance—apart from adjustment for degrees of freedom used in estimating  $\sigma^2$ .

In a system of simultaneous equations, we wish to estimate the parameters in

$$\sum_{j=1}^n \beta_{ij} y_{jt} + \sum_{k=1}^m \gamma_{ik} z_{kt} = u_{it}, \quad i = 1, \dots, n.$$

Here we have  $n$  linear simultaneous equations in  $n$  endogenous and  $m$  exogenous variables. The parameters to be estimated are the elements of the  $n \times n$  coefficient matrix

$$\mathbf{B} = (\beta_{ij}),$$

the  $n \times m$  coefficient matrix

$$\mathbf{\Gamma} = (\gamma_{ik}),$$

and the  $n \times n$  variance-covariance matrix

$$\mathbf{\Sigma} = (\sigma_{ij}).$$

The variances and covariances are defined by

$$\sigma_{ij} = E(u_i u_j).$$

A rule of normalization is applied for each equation,

$$\beta_i \Sigma \beta_i' = 1.$$

In practice, one element of  $\beta_i = (\beta_{i1}, \dots, \beta_{in})$  in each equation is singled out and assigned a value of unity.

The likelihood function for the whole system is

$$L = \text{mod } |\mathbf{B}|^T \left( \frac{1}{\sqrt{2\pi}} \right)^{Tn} |\mathbf{\Sigma}|^{-Tn/2} \times \exp \left\{ -\frac{1}{2} \sum_{t=1}^T [(\mathbf{B} \mathbf{y}_t' + \mathbf{\Gamma} \mathbf{z}_t')' \mathbf{\Sigma}^{-1} (\mathbf{B} \mathbf{y}_t' + \mathbf{\Gamma} \mathbf{z}_t')] \right\},$$

where  $\mathbf{y}_t = (y_{1t}, \dots, y_{nt})$ ,  $\mathbf{z}_t = (z_{1t}, \dots, z_{mt})$ ,  $|\mathbf{\Sigma}|$  is the determinant of  $\mathbf{\Sigma}$ , and  $\text{mod } |\mathbf{B}|$  is the absolute value of the determinant of  $\mathbf{B}$  (Koopmans et al. 1950). The matrix  $\mathbf{B}$  enters this expression as the Jacobian of the transformation from the variables  $u_{1t}, \dots, u_{nt}$  to  $y_{1t}, \dots, y_{nt}$ . The problem of maximum likelihood estimation is to maximize  $L$  or  $\log L$  with respect to the elements of  $\mathbf{B}$ ,  $\mathbf{\Gamma}$ , and  $\mathbf{\Sigma}$ . This is especially difficult compared with the similar problem for single equations shown above, because  $\log L$  is highly nonlinear in the unknown parameters, a difficult source of nonlinearity coming from the Jacobian expression  $\text{mod } |\mathbf{B}|$ .

Maximizing  $\log L$  with respect to  $\mathbf{\Sigma}^{-1}$ , we obtain the maximum likelihood estimator of  $\mathbf{\Sigma}$ , which is

$$\hat{\mathbf{\Sigma}} = (\mathbf{B} \mathbf{\Gamma}) \mathbf{M} (\mathbf{B} \mathbf{\Gamma})',$$

where  $\mathbf{M}$  is the moment matrix of the observations, i.e.,

$$M = \frac{1}{T} \begin{bmatrix} y_{11} & \cdots & y_{1T} \\ \vdots & & \vdots \\ y_{n1} & \cdots & y_{nT} \\ \hline z_{11} & \cdots & z_{1T} \\ \vdots & & \vdots \\ z_{m1} & \cdots & z_{mT} \end{bmatrix} \begin{bmatrix} y_{11} & \cdots & y_{n1} & | & z_{11} & \cdots & z_{m1} \\ \vdots & & \vdots & | & \vdots & & \vdots \\ y_{1T} & \cdots & y_{nT} & | & z_{1T} & \cdots & z_{mT} \end{bmatrix}$$

$$= \begin{bmatrix} M_{yy} & M_{yz} \\ M_{zy} & M_{zz} \end{bmatrix}.$$

Substitution of  $\hat{\Sigma}$  into the likelihood function yields the concentrated form of the likelihood function

$$\log L = \text{Const.} + T \log \text{mod } |\mathbf{B}| - (T/2) \log |\hat{\Sigma}|,$$

where Const. is a constant. Hence, we seek estimators of  $\mathbf{B}$  and  $\Gamma$  that maximize

$$\log \text{mod } |\mathbf{B}| - \frac{1}{2} \log |\hat{\Sigma}| \\ = \log \text{mod } |\mathbf{B}| - \frac{1}{2} \log |(\mathbf{B} \Gamma) \mathbf{M} (\mathbf{B} \Gamma)'|.$$

In the single-equation case we minimize the one-element variance expression, written as a function of the  $\alpha_i$ . In the simultaneous equation case, we maximize  $\log \text{mod } |\mathbf{B}| - \frac{1}{2} \log |\hat{\Sigma}|$ , but this can be shown to be equivalent (Chow 1964) to minimization of  $|\hat{\Sigma}|$ , subject to the normalization rule

$$|\mathbf{B} \mathbf{M}_{yy} \mathbf{B}'| = C,$$

where  $C$  is a constant. This normalization is direction normalization, and as long as it is taken into account, scale normalization (such as  $\beta_{ii} = 1$ , cited previously) is arbitrary. Viewed in this way, the method of maximum likelihood applied to a system of equations appears to be a natural generalization of the method of maximum likelihood applied to a single equation, in which case we minimize  $\sigma^2$  subject to a direction-normalization rule.

*Recursive systems.* The concentrated form of the likelihood function shows clearly that a new element is introduced into the estimation process, through the presence of the Jacobian determinant, which makes calculations of the maximizing values of  $\mathbf{B}$  and  $\Gamma$  highly nonlinear. It is therefore worthwhile to search for special situations in which estimation methods simplify at least to the point of being based on linear calculations.

It is evident that the concentrated form of the likelihood function would lend itself to simpler methods of estimating  $\mathbf{B}$  and  $\Gamma$  if  $|\mathbf{B}|$  were a known constant. This would be the case if  $\mathbf{B}$  were triangular, for then, by a scale normalization, we

would have  $\beta_{ii} = 1$  and  $|\mathbf{B}| = 1$ . If  $\mathbf{B}$  is triangular, the system of equations is called a recursive system. We then simply minimize  $|\hat{\Sigma}|$  with respect to the unknown coefficients; this can be looked upon as a generalized variance minimization, an obvious analogue of least squares applied to a single equation.

If, in addition, it can be assumed that  $\Sigma$  is diagonal, maximum likelihood estimators become a series of successive single-equation least squares estimators. Since the matrix  $\mathbf{B}$  is assumed to be triangular, there must be an equation with only one unlagged endogenous variable. This variable (with unit coefficient) is to be regressed on all the predetermined variables in that equation. Next, there will be an equation with one new endogenous variable. This variable is regressed on the preceding endogenous variable and all the predetermined variables in that equation. In the third equation, another new endogenous variable is introduced. It is regressed on the two preceding endogenous variables and all the predetermined variables in that equation, and so on.

If  $\Sigma$  is not diagonal, a statistically consistent procedure would be to use values of the endogenous variables computed from preceding equations in the triangular array instead of using their actual values. Suppose one equation in the system specifies  $y_1$  as a function of certain  $z$ 's. We would regress  $y_1$  on these  $z$ 's and then compute values of  $y_1$  from the relation

$$\hat{y}_{1t} = \sum_{k=1}^m \hat{\gamma}_{1k} z_{kt},$$

where the  $\hat{\gamma}_{1k}$  are the least squares regression estimators of the  $\gamma_{1k}$ . (Some of the  $\gamma_{1k}$  are zero, as a result of the identifying restrictions imposed prior to computing the regression.) Suppose a second equation in the system specifies  $y_2$  as a function of  $y_1$  and certain  $z$ 's. Our next step would be to regress  $y_2$  on  $\hat{y}_1$  and the included  $z$ 's and then compute values of  $y_2$  from the relation

$$\hat{y}_{2t} = \beta_{21} \hat{y}_{1t} + \sum_{k=1}^m \hat{\gamma}_{2k} z_{kt}.$$

The procedure would be continued until all  $n$  equations are estimated.

Methods of dealing with recursive systems have been studied extensively by Wold, and a summary appears in Strotz and Wold (1960). A recursive system without a diagonal  $\Sigma$ -matrix is found in Barger and Klein (1954). One of the most familiar types of recursive systems studied in econometrics is the cobweb model of demand and supply for agricultural products [see BUSINESS CYCLES, article on MATHEMATICAL MODELS].

*Limited-information maximum likelihood.* Another maximum likelihood approach that is widely used is the limited-information maximum likelihood method. It does not hinge on a specific formulation of the model, as do methods for recursive systems; it is a simplified method because it neglects information. As we have seen, identifying restrictions for an equation takes the form of specifying zero values for some parameters or of imposing certain linear relations on some parameters. The term "limited information" refers to the fact that only the restrictions relating to the particular equation (or subset of equations) being estimated are used. Restrictions on other equations in the system are ignored when a particular equation is being estimated.

Let us again consider the linear system

$$B y_i' + \Gamma z_i' = u_i'.$$

These equations make up the *structural form* of the system and are referred to as structural equations. We denote the *reduced form* of this system by

$$y_i' = -B^{-1}\Gamma z_i' + B^{-1}u_i'$$

or

$$y_i' = \Pi z_i' + v_i'.$$

From the reduced form equations select a subset corresponding to the  $n_i$  endogenous variables in a particular structural equation, say equation  $i$ , which is

$$\sum_{j=1}^{n_i} \beta_{ij} y_{jt} + \sum_{k=1}^{m_i} \gamma_{ik} z_{kt} = u_{it}.$$

The summation limit  $m_i$  indicates the number of predetermined variables included in this equation; we have excluded all zero elements in  $\gamma_i$  and indexed the  $z$ 's accordingly. Form the joint distribution of  $v_{1t}, \dots, v_{n_i t}$  over the sample observations and maximize it with respect to the unknown parameters in the  $i$ th structural equation, subject to the restrictions on this equation alone. The restrictions usually take the form

$$0 = \sum_{j=1}^{n_i} \beta_{ij} \pi_{jk}, \quad k = m_i + 1, \dots, m,$$

where there are  $m$  predetermined variables in the whole system; that is, the  $\gamma_{ik}$ ,  $k = m_i + 1, \dots, m$ , are specified to be zero. The estimated coefficients,  $\beta_{ij}$ ,  $\hat{\gamma}_{ik}$ , and  $\hat{\sigma}_i^2$ , obtained from this restricted likelihood maximization are the limited-information estimators. Methods of obtaining these estimators and a study of their properties are given in Anderson and Rubin (1949).

Linear regression calculations are all that are needed in this type of estimation, save for the ex-

traction of a characteristic root of a matrix with dimensionality  $n_i \times n_i$ . A quickly convergent series of iterations involving matrix multiplication leads to the computation of this root and associated vector. The vector obtained, properly normalized by making one coefficient unity, provides estimates of the  $\beta_{ij}$ . The estimates of the  $\gamma_{ik}$  are obtained from

$$\hat{\gamma}_{ik} = - \sum_{j=1}^{n_i} \beta_{ij} \hat{\pi}_{jk}, \quad k = 1, \dots, m_i,$$

where the  $\hat{\pi}_{jk}$  are least squares regression coefficients from the reduced form equations.

It is significant that both full-information and limited-information maximum likelihood estimators are *essentially* unchanged no matter which variable is selected to have a unit coefficient in each equation. That is to say, if we divide through an estimated equation by the coefficient of any endogenous variable, we get a set of coefficients that would have been obtained by applying the estimation methods under the specification that the same variable have the unit coefficient. Full-information and limited-information maximum likelihood estimators are invariant under this type of scale normalization. Other estimators are not.

**Two-stage least squares.** The classical method of least squares multiple regression applied to a single equation that is part of a larger simultaneous system is inconsistent by virtue of the fact that some of the "explanatory" variables in the regression (the variables with unknown coefficients) may not be independent of the error variable. If we can "purify" such variables to make them independent of the error terms, we can apply ordinary least squares methods to the transformed variables. The method of two-stage least squares does this for us.

Let us return to the equation estimated above by limited information. Choose  $y_1$ , say, as the dependent variable, that is, set  $\beta_{11}$  equal to unity. In place of  $y_{2t}, \dots, y_{n_i t}$ , we shall use

$$\hat{y}_{jt} = \sum_{k=1}^{m_i} \hat{\pi}_{jk} z_{kt}, \quad j = 2, \dots, n_i,$$

as explanatory variables. The  $\hat{y}_{jt}$  are *computed* values from the least squares regressions of  $y_j$  on all the  $z_k$  in the system ( $k = 1, \dots, m_i$ ). The coefficients  $\hat{\pi}_{jk}$  are the computed regression coefficients. The regression of  $y_1$  on  $\hat{y}_2, \dots, \hat{y}_{n_i}, z_1, \dots, z_{m_i}$ , provides a two-stage least squares estimator of the single equation. All the equations of a system may be estimated in this way. This can be seen to be a generalization, to systems with nontriangular Jacobians, of the method suggested previously for recursive models in which the variance-covariance matrix of disturbances is not diagonal.

We may write the "normal" equations for these least squares estimators as

$$\begin{bmatrix} \sum_{t=1}^T y_{1t} \hat{y}'_t \\ \sum_{t=1}^T y_{1t} \mathbf{z}'_t \end{bmatrix} = \begin{bmatrix} \mathbf{M}_{\hat{y}\hat{y}} & \mathbf{M}_{\hat{y}\mathbf{z}} \\ \mathbf{M}_{\mathbf{z}\hat{y}} & \mathbf{M}_{\mathbf{z}\mathbf{z}} \end{bmatrix} \begin{bmatrix} -\mathbf{b}' \\ -\mathbf{c}' \end{bmatrix}.$$

In this notation  $\hat{\mathbf{y}}_t$  is the vector of computed values ( $\hat{y}_{2t}, \dots, \hat{y}_{n_t t}$ );  $\mathbf{z}_t$  is the vector ( $z_{1t}, \dots, z_{m_t t}$ );

$$\begin{bmatrix} \mathbf{M}_{\hat{y}\hat{y}} & \mathbf{M}_{\hat{y}\mathbf{z}} \\ \mathbf{M}_{\mathbf{z}\hat{y}} & \mathbf{M}_{\mathbf{z}\mathbf{z}} \end{bmatrix} = \begin{bmatrix} \hat{y}_{21} \cdots \hat{y}_{2T} \\ \vdots \\ \hat{y}_{n_1 1} \cdots \hat{y}_{n_1 T} \\ \hline z_{11} \cdots z_{1T} \\ \vdots \\ z_{m_1 1} \cdots z_{m_1 T} \end{bmatrix} \begin{bmatrix} \hat{y}_{21} \cdots \hat{y}_{n_1 1} & z_{11} \cdots z_{m_1 1} \\ \vdots & \vdots \\ \hat{y}_{2T} \cdots \hat{y}_{n_1 T} & z_{1T} \cdots z_{m_1 T} \end{bmatrix};$$

$\mathbf{b}$  is the estimator of the vector ( $\beta_{12}, \dots, \beta_{1n_1}$ ); and  $\mathbf{c}$  is the estimator of the vector ( $\gamma_{11}, \dots, \gamma_{1m_1}$ ). It should be noted that  $\mathbf{M}_{\hat{y}\mathbf{z}} = \mathbf{M}_{\mathbf{z}\hat{y}} = \mathbf{M}'_{\mathbf{z}\hat{y}}$ . It should be further observed that

$$\mathbf{M}_{\hat{y}\hat{y}} = \mathbf{M}_{\mathbf{y}\mathbf{y}} - \mathbf{M}_{\mathbf{y}\mathbf{z}} \mathbf{M}_{\mathbf{z}\mathbf{z}}^{-1} \mathbf{M}_{\mathbf{z}\mathbf{y}}.$$

In this expression the whole vector  $\mathbf{z}_t = (z_{1t}, \dots, z_{m_t t})$ , which includes all the predetermined variables in the system, is used for the evaluation of the relevant moment matrices.

**k-Class estimators.** Theil (1958) and Basmann (1957), independently, were the first to advocate the method of two-stage least squares. Theil suggested a whole system of estimators, called the *k*-class. He defined these as the solutions to

$$\begin{bmatrix} \sum_{t=1}^T y_{1t} \mathbf{y}'_t - k \sum_{t=1}^T y_{1t} \hat{\mathbf{y}}'_t \\ \sum_{t=1}^T y_{1t} \mathbf{z}'_t \end{bmatrix} = \begin{bmatrix} \mathbf{M}_{\mathbf{y}\mathbf{y}} - k \mathbf{M}_{\mathbf{y}\hat{\mathbf{y}}} \mathbf{M}_{\hat{\mathbf{y}}\hat{\mathbf{y}}}^{-1} \mathbf{M}_{\hat{\mathbf{y}}\mathbf{y}} & \mathbf{M}_{\mathbf{y}\mathbf{z}} \\ \mathbf{M}_{\mathbf{z}\mathbf{y}} & \mathbf{M}_{\mathbf{z}\mathbf{z}} \end{bmatrix} \begin{bmatrix} -\mathbf{b}' \\ -\mathbf{c}' \end{bmatrix}.$$

In this expression  $\hat{\mathbf{y}}_t$  is the vector of residuals computed from the reduced form regressions of  $y_{2t}, \dots, y_{n_t t}$  on all the  $z_{kt}$ . If  $k = 0$ , we have ordinary least squares estimators. If  $k = 1$ , we have two-stage least squares estimators. If  $k = 1 + \lambda$  and  $\lambda$  is the smallest root of the determinantal equation

$$|\mathbf{M}_{\mathbf{y}\mathbf{y}} \mathbf{M}_{\mathbf{z}\mathbf{z}}^{-1} \mathbf{M}_{\mathbf{z}\mathbf{y}} - \mathbf{M}_{\mathbf{y}\mathbf{y}} \mathbf{M}_{\mathbf{y}\hat{\mathbf{y}}}^{-1} \mathbf{M}_{\hat{\mathbf{y}}\mathbf{y}} - \lambda (\mathbf{M}_{\mathbf{y}\mathbf{y}} - \mathbf{M}_{\mathbf{y}\hat{\mathbf{y}}} \mathbf{M}_{\hat{\mathbf{y}}\hat{\mathbf{y}}}^{-1} \mathbf{M}_{\hat{\mathbf{y}}\mathbf{y}})| = 0,$$

we have limited-information maximum likelihood estimators. This is a succinct way of showing the relationships between various single-equation methods of estimation. Of these three members of the *k*-class, ordinary least squares is not consistent; the other two are.

**Three-stage least squares.** Other members of the *k*-class could be cited for special discussion, but a more fruitful generalization of Theil's approach to estimation theory lies in the direction of what he and Zellner (see Zellner & Theil 1962) call three-stage least squares. Chow (1964) has shown that three-stage least squares estimators are better viewed as simultaneous two-stage least squares estimators. Let us denote  $\hat{\mathbf{u}}_t$  as the vector of residuals associated with each equation in a system that has had elements of  $y_{it}$  replaced by  $\hat{y}_{it}$ , that is,  $\hat{\mathbf{u}}_t = (\hat{u}_{1t}, \dots, \hat{u}_{n_t t})$ , where

$$\hat{u}_{it} = \hat{y}_{it} + \sum_{j=1}^n \beta_{ij} \hat{y}_{jt} + \sum_{k=1}^m \gamma_{ik} z_{kt}.$$

In this formulation  $\sum'$  means summation over all values of *j* except *j* = *i*, and it is assumed that the *i*th endogenous variable in the *i*th equation has a unit coefficient. Some elements of  $\beta_{ij}$  and  $\gamma_{ik}$  are zero or otherwise restricted for identification. Define

$$\hat{\Sigma} = \begin{bmatrix} \hat{u}_{11} \cdots \hat{u}_{1T} \\ \vdots \\ \hat{u}_{n_1 1} \cdots \hat{u}_{n_1 T} \end{bmatrix} \begin{bmatrix} \hat{u}_{11} \cdots \hat{u}_{n_1 1} \\ \vdots \\ \hat{u}_{1T} \cdots \hat{u}_{n_1 T} \end{bmatrix}.$$

Minimization of  $|\hat{\Sigma}|$  with respect to  $\beta_{ij}$  and  $\gamma_{ik}$  yields the estimators sought. Thus, we have an extension of the principle of least squares in which the generalized variance is minimized. This is like the principle of maximum likelihood, which also minimizes  $|\Sigma|$ , expressed in terms of the  $\beta_{ij}$  and  $\gamma_{ik}$ , but the direction normalization is different.

Theil and Zellner termed their method three-stage least squares because they first derived two-stage least squares estimators for each single equation in the system. They computed the residual variance for each equation and used these as estimators of the variances of the true (unobserved) random disturbances. They then used Aitken's

generalized method of least squares (1935) to estimate all the equations in the system simultaneously. Aitken's method applies to systems of equations in which the variance-covariance matrix for disturbances is a general known positive definite matrix. Theil and Zellner used the two-stage estimator of this variance-covariance matrix as though it were known. The advantage of this method is that it is of the full-information variety, making use of restrictions on all the equations of the system.

**Other methods.** If the conditions for identification of a single equation are such that there are just enough restrictions to transform linearly and uniquely the reduced form coefficients into the structural coefficients, an indirect least squares method of estimation can be used. Exact identification under zero-type restrictions would enable one to solve

$$0 = \sum_{j=1}^n \beta_{ij} \pi_{jk}, \quad k = m_1 + 1, \dots, m,$$

for a unique set of estimated  $\beta_{ij}$ , apart from scale normalization, given a set of estimated  $\pi_{jk}$ . The latter would be determined from least squares estimators of the reduced forms. Since there are  $n_1 - 1$  of the  $\beta_{ij}$  to be determined, the necessary condition for exact identification here is that  $n_1 - 1 = m - m_1$ .

If there is *underidentification*, i.e., too few a priori restrictions, structural estimation cannot be completed but unrestricted reduced forms can be estimated by the method of least squares. This is the most information that the econometrician can extract when there is lack of identification. Least squares estimators of the reduced form equations are consistent in the underidentified case, but estimates of the structural parameters cannot be made.

**Instrumental variables.** The early discussion of estimation problems in simultaneous equation models contained, on many occasions, applications of a method known as the method of instrumental variables. In estimating the  $i$ th equation of a linear system, i.e.,

$$\sum_{j=1}^{n_1} \beta_{ij} y_{jt} + \sum_{k=1}^{m_1} \gamma_{ik} z_{kt} = u_{it},$$

we may choose  $(n_1 - 1) + m_1$  variables that are independent of  $u_{it}$ . These are known as the instrumental set. Naturally, the exogenous variables in the equation ( $z_{1t}, \dots, z_{m_1 t}$ ) are possible members of this set. In addition, we need  $n_1 - 1$  more instruments from the list of exogenous variables in the system but not in the  $i$ th equation. For this problem let these be denoted as  $x_{2t}, \dots, x_{n_1 t}$ . Since

$E(z_{st} u_{it}) = 0$ ,  $s = 1, \dots, m_1$ , and  $E(x_{rt} u_{it}) = 0$ ,  $r = 2, \dots, n_1$ , we can estimate the unknown parameters from

$$\sum_{j=1}^{n_1} \beta_{ij} \sum_{t=1}^T y_{jt} x_{rt} + \sum_{k=1}^{m_1} \gamma_{ik} \sum_{t=1}^T z_{kt} x_{rt} = 0, \quad r = 2, \dots, n_1,$$

$$\sum_{j=1}^{n_1} \beta_{ij} \sum_{t=1}^T y_{jt} z_{st} + \sum_{k=1}^{m_1} \gamma_{ik} \sum_{t=1}^T z_{kt} z_{st} = 0, \quad s = 1, \dots, m_1.$$

With a scale-normalization rule, such as  $\beta_{i1} = 1$ , we have  $(n_1 - 1) + m_1$  linear equations in the same number of unknown coefficients. In exactly identified models there is no problem in picking the  $x_{rt}$ , for there will always be exactly  $n_1 - 1$   $z$ 's excluded from the  $i$ th equation. The method is then identical with indirect least squares. If  $m - m_1 > n_1 - 1$ , i.e., if there are more exogenous variables outside the  $i$ th equation than there are endogenous variables minus one, we have overidentification, and the number of possible instrumental variables exceeds the minimum needed. In order to avoid the problem of subjective or arbitrary choice among instruments, we turn to the methods of limited information or two-stage least squares. In fact, it is instructive to consider how the method of two-stage least squares resolves this matter. In place of single variables as instruments, it uses linear combinations of them. The computed values

$$\hat{y}_{jt} = \sum_{k=1}^m \hat{\pi}_{jk} z_{kt}, \quad j = 2, \dots, n_1,$$

are the new instruments. We can view the method either as the regression of  $y_i$  on  $\hat{y}_2, \dots, \hat{y}_{n_1}$ ,  $z_1, \dots, z_{m_1}$ , or as instrumental-variable estimators with  $\hat{y}_{2t}, \dots, \hat{y}_{n_1 t}$ ,  $z_{1t}, \dots, z_{m_1 t}$  as the instruments. Both come to the same thing. The method of instrumental variables yields consistent estimators.

**Subgroup averages.** The instrumental-variables method can be applied in different forms. One form was used by Wald (1940) to obtain consistent estimators of a linear relationship between two variables each of which is subject to error. This gives rise to a method that can be used in estimating econometric systems. Wald proposed that the estimator of  $\beta$  in

$$y_t = \alpha + \beta x_t,$$

where  $y_t$  and  $x_t$  are both measured with error, be computed from

$$\hat{\beta} = \frac{\sum_{t=\frac{T}{2}+1}^T y_t - \frac{T}{2} \bar{y}}{\sum_{t=\frac{T}{2}+1}^T x_t - \frac{T}{2} \bar{x}}.$$

He proposed ordering the sample in ascending magnitudes of the variable  $x$ . From two halves of the sample, we determine two sets of mean values of  $y$  and  $x$ . The line joining these means will have a slope given by  $\beta$ . Wald showed the conditions under which these estimates are consistent.

This may be called the method of subgroup averages. It is a very simple method, which may readily be applied to equations with more than two parameters. The sample is split into as many groups as there are unknown parameters to be determined in the equation under consideration. If there are three parameters, for example, the sample may be split into thirds and the parameters estimated from

$$\begin{aligned}\bar{y}_1 &= \alpha + \beta \bar{x}_1 + \gamma \bar{z}_1, \\ \bar{y}_2 &= \alpha + \beta \bar{x}_2 + \gamma \bar{z}_2, \\ \bar{y}_3 &= \alpha + \beta \bar{x}_3 + \gamma \bar{z}_3.\end{aligned}$$

The extension to more parameters is obvious. The method of subgroup averages can be shown to be a form of the instrumental-variables method by an appropriate assignment of values to "dummy" instrumental variables.

Subgroup averages is a very simple method, and it is consistent, but it is not very efficient.

*Simultaneous least squares.* The simultaneous least squares method, suggested by Brown (1960), minimizes the sum of squares of all reduced form disturbances, subject to the parameter restrictions imposed on the system, i.e., it minimizes

$$\sum_{i=1}^T \sum_{t=1}^n v_{it}^2,$$

subject to restrictions. Suppose that the  $v_{it}$  are expressed as functions of the observables and parameters, with all restrictions included; then Brown's method minimizes the sum of the elements on the main diagonal of  $\Sigma_v$ , where  $\Sigma_v$  is the variance-covariance matrix of reduced form disturbances, whereas full-information maximum likelihood minimizes  $|\Sigma_v|$ .

Brown's method has the desirable property of being a full-information method; it is distribution free; it is consistent; but it has the drawback that its results are not invariant under linear transformations of the variables. This drawback can be removed by expressing the reduced form disturbance in standard units

$$v'_{it} = v_{it}/\sigma_{y_i}$$

and minimizing

$$\sum_{i=1}^T \sum_{t=1}^n (v'_{it})^2.$$

## Evaluation of alternative methods

The various approaches to estimation of whole systems of simultaneous equations or individual relationships within such systems are *consistent* except for the single-equation least squares method. If the system is recursive and disturbances are independent between equations, least squares estimators are also consistent. In fact, they are maximum likelihood estimators for normally distributed disturbances. But generally, ordinary least squares estimators are not consistent. They are included in the group of alternatives considered here because they have a time-honored status and because they have minimum variance. In large-sample theory, maximum likelihood estimators of parameters are generally efficient compared with all other estimators. That is why we choose full-information maximum likelihood estimators as norms. They are consistent and efficient. Least squares estimators are minimum-variance estimators if their variances are estimated about estimated (inconsistent) sample means. If their variances are measured about the *true*, or population, values, it is not certain that they are efficient.

Limited-information estimators are less efficient than full-information maximum likelihood estimators. This should be intuitively obvious, since full-information estimators make use of more a priori information; it is proved in Klein (1960). Two-stage least squares estimators have asymptotically the same variance-covariance matrix as limited-information estimators, and three-stage (or simultaneous two-stage) least squares estimators have the same variance-covariance matrix as full-information maximum likelihood estimators. Thus, asymptotically the two kinds of limited-information estimators have the same efficiency, and the two kinds of full-information estimators have the same efficiency. The instrumental-variables or subgroup-averages methods are generally inefficient. Of course, the instrumental-variables method can be pushed to the point where it is the same as two-stage least squares estimation and can thereby gain efficiency.

A desirable aspect of the method of maximum likelihood is that its properties are preserved under a single-valued transformation. Thus, efficient estimators of structural parameters by this method transform into efficient estimators of reduced form parameters. The apparently efficient method of least squares may lose its efficiency under this kind of transformation. In applications of models, we use the reduced form in most cases, not the individual structural equations; therefore the prop-

erties under conditions of transformation from structural to reduced form equations are of extreme importance. Limited-information methods are a form of maximum likelihood methods. Therefore the properties of limited information are preserved under transformation.

To obtain limited-information estimators of the single equation

$$\sum_{j=1}^{n_1} \beta_{ij} y_{jt} + \sum_{k=1}^{m_1} \gamma_{ik} z_{kt} = u_{it},$$

we maximize the joint likelihood of  $v_{1t}, \dots, v_{n_1t}$  in

$$y_{jt} = \sum_{i=1}^m \pi_{ji} z_{it} + v_{jt}, \quad j = 1, \dots, n_1,$$

subject to the restrictions on the  $i$ th equation. In this case only the  $n_1$  reduced forms corresponding to  $y_{1t}, \dots, y_{n_1t}$  are used. It is also possible to simplify calculations, and yet preserve consistency (although at the expense of efficiency), by using fewer than all  $m$  predetermined variables in the reduced forms. In this sense the reduced forms of limited-information estimation are not necessarily unique, and the same endogenous variable appearing in different structural equations of a system may not have the same reduced form expression for each equation estimator. There is yet another sense in which we may derive reduced forms for the method of limited information. After each equation of a complete system has been estimated by the method of limited information, we can derive algebraically a set of reduced forms for the whole system. These would, in fact, be the reduced forms used in forecasting, multiplier analysis, and similar applications of systems. The efficiency property noted above for limited and full information has not been proved for systems of this type of reduced forms, but this has been studied in numerical analysis (see below).

**Ease of computation.** Finally we come to an important practical matter in the comparison of the different methods of estimation—relative ease of computation. Naturally, calculations are simpler and smaller in magnitude for single-equation least squares than for any of the other methods except that of subgroup averages. The method of instrumental variables is of similar computational complexity, but for equations with four or more variables it pays to have the advantage of symmetry in the moment matrices, as is the case with single-equation least squares. This is hardly a consideration with modern electronic computing machines, but it is worth consideration if electric desk machines are being used.

The next-simplest calculations are those for two-

stage least squares. These consist of a repeated application of least squares regression techniques of calculation, but the first regressions computed are of substantial size. There are as many independent variables in the regression as there are predetermined variables in the system, provided there are enough degrees of freedom. Essentially, the method amounts to the calculation of parameters and computed dependent variables in

$$\hat{y}_{jt} = \sum_{k=1}^m \hat{\pi}_{jk} z_{kt}, \quad j = 2, \dots, n_1.$$

Only the "forward" part of this calculation by the standard Gauss–Doolittle method need be made in order to obtain the moment matrix of the  $y_{jt}$ . In the next stage we compute the regression

$$y_{1t} = - \sum_{j=2}^{n_1} b_{1j} \hat{y}_{jt} - \sum_{k=1}^{m_1} c_{1k} z_{kt}.$$

Two important computing problems arise in the first stage. In many systems  $m > T$ ; i.e., there are insufficient degrees of freedom in the sample for evaluation of the reduced forms. We may choose a subset of the  $z_{kt}$ , or we may use principal components of the  $z_{kt}$  (Kloek & Mennes 1960). Systematic and efficient ways of choosing subsets of the  $z_{kt}$  have been developed by taking account of the recursive structure of the model (Fisher 1965). In many economic models  $m$  has been as large as 30 or more, and it is often difficult to make sufficiently accurate evaluation of the reduced form regression equations of this size, given the amount of multicollinearity found in economic data with common trends and cycles. The same procedures used in handling the degrees-of-freedom problem are recommended for getting round the difficulties of multicollinearity. Klein and Nakamura (1962) have shown that multicollinearity problems are less serious in ordinary than in two-stage least squares. They have also shown that these problems increase as we move on to the methods of limited-information and then full-information maximum likelihood.

Limited-information methods require all the computations of two-stage least squares and, in addition, the extraction of a root of an  $n_1 \times n_1$  determinantal equation. The latter calculation can be done in a straightforward manner by iterative matrix multiplication, usually involving fewer than ten iterations.

Both limited information and two-stage least squares are extremely well adapted to modern computers and can be managed without much trouble on electric desk machines.

Three-stage least squares estimators involve the

computation of two-stage estimators for each equation of a system, estimation of a variance-covariance matrix of structural disturbances, and simultaneous solution of a linear equation system of the order of all coefficients in the system. This last step may involve a large number of estimating equations for a model of 30 or more structural equations.

All the previous methods consist of standard linear matrix operations. The extraction of a characteristic root is the only operation that involves nonlinearities, and the desired root can quickly be found by an iterative process of matrix multiplication. Full-information maximum likelihood methods, however, are quite different. The estimation equations are highly nonlinear. For small systems of two, three, or four equations, estimates have been made without much trouble on large computers (Eisenpress 1962) and on desk machines (Chernoff & Divinsky 1953). The problem of finding the maximum of a function as complicated as the joint likelihood function of a system of 15 to 20 or more equations is, however, formidable. Electronic machine programs have been developed for this purpose. The most standardized sets of full-information maximum likelihood calculations are for systems that are fully linear in both parameters and variables. Single-equation methods require linearity only in unknown parameters, and this is a much weaker restriction. Much progress in computation has been made since the first discussion of these econometric methods of estimation, in 1943, but the problem is far from solved, and there is no simple, push-button computation. This is especially true of full-information maximum likelihood.

Efficient programs have recently been developed for calculating full-information maximum likelihood estimates in either linear or nonlinear systems, and these have been applied to models of as many as 15 structural equations, involving more than 60 unknown parameters.

**Generalization of assumptions.** The basis for comparing different estimation methods or for preferring one method over another rests on *asymptotic* theory. The property of consistency is a large-sample property, and the sampling errors used to evaluate efficiency measures are asymptotic formulas. Unfortunately, samples of economic data are frequently not large, especially time series data. The amount of small-sample bias or the small-sample confidence intervals for parameter estimators are not generally known in specific formulas. Constructed numerical experiments, designed according to Monte Carlo methods, have

thrown some light on the small-sample properties. These are reported below.

Another assumption sometimes made for the basic model is that the error terms are mutually independent. We noted above that successive least squares treatment of equations in recursive systems is identical with maximum likelihood estimation when the variance-covariance matrix of structural disturbances is diagonal. This implies mutual independence among contemporaneous disturbances. In a time series model we usually make another assumption, namely, that

$$E(u_{it}, u_{jt'}) = 0, \quad t \neq t', \text{ for all } i, j.$$

The simplest way in which this assumption can be modified is to allow the errors to be related in some linear autoregressive process, such as

$$u_{it} = \sum_{j=1}^n \sum_{k=1}^p \rho_{ijk} u_{jt, t-k} + e_{it}, \quad i = 1, 2, \dots, n,$$

where  $E(e_{it}, e_{jt'}) = 0$  ( $t \neq t'$ , for all  $i, j$ ). In a formal sense joint maximum likelihood estimation of structural parameters and autoregressive coefficients,  $\rho_{ijk}$ , can be laid out in estimation equations, but there are no known instances where these have been solved on a large scale, for the estimation equations are very complicated. For single-equation models or for recursive systems which split into a series of single-equation regressions, the autoregressive parameters of first order have been jointly estimated with structural parameters (Barger & Klein 1954). The principal extensions to larger systems have been in cases where the autoregressive parameters are known *a priori*. Then it is easy to make known autoregressive transformations of the variables and proceed as in the case of independent disturbances. [See TIME SERIES.]

Related to the above two points is the treatment of lagged values of endogenous variables as predetermined variables. The presence of lagged endogenous variables reflects serial correlation among endogenous variables rather than among disturbances. In large samples it can be shown that for purposes of estimation we are justified in treating lagged variables as predetermined, but in small samples we incur bias on this account.

Another assumption regarding the disturbances in simultaneous equation systems is that they are mainly due to neglected or unmeasurable variables that affect or disturb each equation of the model. They are regarded as errors in behavior or technology. From a formal mathematical point of view, they could equally well be regarded as a direct error in observation of the normalized dependent variable in each equation, assuming that the system is

written so that there is a different normalized dependent variable in each equation. There is an implicit assumption that the exogenous variables are measured without error. If we change the model to one in which random errors enter through disturbances to each relation and also through inaccurate observation of each individual variable, we have a more complicated probability scheme, whose estimation properties have not been developed in full generality. This again has been a case for numerical treatment by Monte Carlo methods.

The procedures of estimating simultaneous equation models as though errors are mutually independent when they really are not and as though variables are accurately measured when they really are not are *specification errors*. Other misspecifications of models can occur. For simplicity we assume linearity or, at least, linearity in unknown parameters, but the true model may have a different functional form. Errors may not follow the normal distribution, as we usually assume. [See ERRORS, article on EFFECTS OF ERRORS IN STATISTICAL ASSUMPTIONS.]

Full-information methods are sensitive to specification error because they depend on restrictions imposed throughout an entire system. Single-equation methods depend on a smaller set of restrictions. If an investigator has particular interest in just one equation or in a small sector of the economy, he may incur large specification error by making too superficial a study of the parts of the economy that do not particularly interest him. There is much to be said for using single-equation methods (limited information or two-stage least squares) in situations where one does not have the resources to specify the whole economy adequately.

There are numerous possibilities for specifying models incorrectly. These probably introduce substantial errors in applied work, but they cannot be studied in full generality for there is no particular way of showing all the misspecifications that can occur. We can, however, construct artificial numerical examples of what we believe to be the major specification errors. These are discussed below.

**Sampling experiments.** The effect on estimation methods of using simplified assumptions that are not fully met in real life often cannot be determined by general mathematical analysis. Econometricians have therefore turned to constructing sampling experiments with large-scale computers to test proposed methods of estimation where (1) the sample is small; and (2) there is specification error in the statement of the model, such as

(a) nonzero parameters assumed to be zero, (b) dependent exogenous variables and errors assumed to be independent, (c) imperfectly measured exogenous variables assumed to be perfectly measured, or (d) serially correlated errors assumed to be not serially correlated.

So-called Monte Carlo methods are used to perform the sampling experiments that conceptually underlie sampling error calculations. These sampling experiments are never, in fact, carried out with nonexperimental sources of data, for we cannot relive economic life over and over again; but we can instruct a machine to simulate such an experiment.

Consider a single equation to be estimated by different methods, for example,

$$y_t = \alpha + \beta x_t + u_t, \quad t = 1, 2, \dots, T.$$

Fix  $\alpha$  and  $\beta$  at, say, 3.0 and 0.5, respectively, and set  $T = 30$ . This would correspond to the process

$$y_1 = 3.0 + 0.5x_1 + u_1$$

$$\vdots \quad \vdots \quad \vdots \quad \vdots$$

$$y_{30} = 3.0 + 0.5x_{30} + u_{30}.$$

We also fix the values of the predetermined variables  $x_1, x_2, \dots, x_{30}$  once and for all. We set  $T = 30$  to indicate that we are dealing with a 30-element small sample. A sample of 30 annual observations would be the prototype.

Employing a source of random numbers scaled to have a realistic standard deviation and a zero mean, we draw a set of random numbers  $u_1, \dots, u_{30}$ . We then instruct a machine to use  $u_1, \dots, u_{30}$  and  $x_1, \dots, x_{30}$  to compute  $y_1, \dots, y_{30}$  from the above formulas. From the samples of data,  $y_1, \dots, y_{30}$  and  $x_1, \dots, x_{30}$ , we estimate  $\alpha$  and  $\beta$  by the methods being studied. Let  $\hat{\alpha}$  and  $\hat{\beta}$  be the estimated values. We then draw a new set of random numbers,  $u_1, \dots, u_{30}$ , and repeat the process, using the same values of  $x_1, \dots, x_{30}$ . From many such repetitions, say 100, we have sampling distributions of  $\hat{\alpha}$  and  $\hat{\beta}$ . Means of these distributions, when compared with  $\alpha (= 3.0)$  and  $\beta (= 0.5)$ , indicate bias, if any, and standard deviations or root-mean-square values about 3.0 or 0.5 indicate efficiency. From these sampling distributions we may compare different estimators of  $\alpha$  and  $\beta$ .

What we have said about this simple type of experiment for a single equation can readily be extended to an entire system:

$$By'_t + \Gamma x'_t = \alpha'_t, \quad t = 1, 2, \dots, T.$$

In this case we must start with assumed values of  $B$  and  $\Gamma$ . We choose a  $T$ -element vector of values

for each element of  $\mathbf{z}_t$ , the predetermined variables, and repeated  $T$ -element vectors of values for each element of  $\mathbf{u}_t$ . The random variables are chosen so that their variance-covariance matrix equals some specified set of values. As in the single-equation case,  $T = 30$  or some likely small-sample value. The  $\mathbf{z}_t$  are often chosen in accordance with the values of predetermined variables used in actual models. In practice, Monte Carlo studies of simultaneous equation models have dealt with small systems having only two, three, or four equations.

Two sets of results are of interest from these studies. Estimates of individual elements in  $\mathbf{B}$  and  $\mathbf{\Gamma}$  can be studied and compared for different estimators: estimates of  $\mathbf{B}^{-1}\mathbf{\Gamma}$ , the reduced-form coefficients, can be similarly investigated. In addition, we could form some over-all summary statistic, such as standard error of forecast, for different estimators.

The simplest Monte Carlo experiments have been made to test for small-sample properties alone; they have not introduced measurement errors, serial correlation of disturbances, or other specification errors. Generally speaking, these studies clearly show the bias in single-equation least squares estimates where some of the "independent" variables in the regression calculation are not independent of the random disturbances. Maximum likelihood estimators (full or limited information) show comparatively small bias. The standard deviations of individual parameter estimators are usually smallest for the single-equation least squares method, but this standard deviation is computed about the biased sample mean. If estimated about the true mean, least squares sometimes does not show up well, indicating that bias outweighs efficiency. Full-information maximum likelihood shows up as an efficient method, whether judged in terms of variation about the sample or the true mean. Two-stage least squares estimators appear to have somewhat smaller variance about the true values than do limited-information estimators, and both methods measure up to the efficiency of single-equation least squares methods when variability is measured about the true mean.

Asymptotically, limited-information and two-stage estimators have the same variance-covariance matrices, and they are both inefficient compared with full-information estimators. The Monte Carlo results for small samples are not surprising, although the particular experiments studied give a slight edge to two-stage estimators.

When specification error is introduced, in the form of making an element of  $\mathbf{\Gamma}$  zero in the estimation process when it is actually nonzero in the

population, we find that full-information methods are very sensitive. Both limited-information and two-stage estimators perform better than full-information maximum likelihood. Two-stage estimators are the best among all methods examined in this situation. Limited-information estimators are very sensitive to intercorrelation among predetermined variables.

The principal result for Monte Carlo estimators of reduced form parameters is that transformed single-equation least squares values lose their efficiency properties. Being seriously biased as well, these estimates show a poor over-all rating when used for estimating reduced forms for a system as a whole. Full-information estimators, which are shown in these experiments to be sensitive to specification error, do better in estimating reduced form coefficients than in estimating structural coefficients. Their gain in making use of all the a priori information outweighs the losses due to the misspecification introduced and, in the end, gives them a favorable comparison with ordinary least squares estimators of the reduced form equations that make no use of the a priori information and have no specification error.

If a form of specification error is introduced in a Monte Carlo experiment by having common time trends in elements of  $\mathbf{z}_t$  and  $\mathbf{u}_t$ , so that they are not independent as hypothesized, we find that limited-information estimators are as strongly biased as are ordinary least squares values. If time trend is introduced as an additional variable, however, the limited-information method has small bias.

When observation errors are imposed on the  $\mathbf{z}_t$ , both least squares and limited-information estimators show little change in bias but increases in sampling errors. In this model, it turns out as before that the superior efficiency of least squares estimators of individual structural parameters does not carry over to the estimators of reduced form parameters.

A comprehensive sampling-experiment study of alternative estimators under correctly specified and under misspecified conditions is given in Summers (1965), and Johnston (1963) compares results from several completed Monte Carlo studies. This approach is in its infancy, and further investigations will surely throw new light on the relative merits of different estimation methods.

For some years economists were digesting the modern approach to simultaneous equation estimation introduced by Haavelmo, Mann and Wald, Anderson and Rubin, and Koopmans, Rubin, and Leipnik, and there was a period of little change in

this field. Since the development of the two-stage least squares method by Theil, there have been a number of developments. The methods are undergoing interpretation and revision. New estimators are being suggested, and it is likely that many new results will be forthcoming in the next few decades. Wold (1965) has proposed a method based on iterative least squares that recommends itself by its adaptability to modern computers, its consistency, and its capacity to make use of a priori information on all equations simultaneously and to treat some types of nonlinearity with ease. Also, excellent recent books, by Christ (1966), Goldberger (1964), and Malinvaud (1964), greatly aid instruction in this subject.

# SIZE DISTRIBUTIONS IN ECONOMICS

The size distributions of certain economic and socioeconomic variables—incomes, wealth, firms, plants, cities, etc.—display remarkably regular patterns. These patterns, or distribution laws, are usually skew, the most important being the Pareto law [see PARETO, *article on CONTRIBUTIONS TO ECONOMICS*] and the log-normal, or Gibrat, law (below). Some disagreement about the patterns actually observed still exists. The empirical distributions often approximate the Gibrat law in the middle ranges of the variables and the Pareto law in the upper ranges. The study of size distributions is concerned with explaining why the observed patterns exist and persist. The answer may be found in the conception of the distribution laws as the steady state equilibria of stochastic processes that describe the underlying economic or demographic forces. A steady state equilibrium is a macroscopic condition that results from the balance of a great number of random microscopic movements proceeding in opposite directions. Thus, in a stationary population a constant age structure is maintained by the annual occurrence of approximately constant numbers of births and deaths—the random events par excellence of human life.

The steady state explanation is evidently inspired by the example of statistical mechanics in which the macroscopic conditions are heat and pressure and the microscopic random movements are performed by the molecules. Characteristically, the steady state is independent of initial conditions, i.e., the initial size distribution. In economic applications this is important because it means that the pattern determined by certain structural constants tends to be re-established after a disturbance is imposed on the process. This will only be the case, however, if the process leading to the steady state is really ergodic, that is, if the influence of initial conditions on the state of the system becomes negligible after a certain time; and it will be relevant in practice only if this time interval is sufficiently short.

The idea that the stable pattern of a distribution might be explained by the interplay of a multitude of small random events was first demonstrated in the case of the normal distribution. The central limit theorem shows that the addition of a great number of small independent random variables yields a variable that is normally distributed, when properly centered and scaled. A stochastic process that leads to a normal distribution is the random walk on a straight line with, for example, a 50 per

cent probability each of a step in one direction and a step in the opposite direction. It is only natural that attempts to explain other distribution patterns should have started from this idea. The first extension was to allow the random walk to proceed on a logarithmic scale. The resulting distribution is log-normal on the natural scale and is known as the log-normal or Gibrat distribution. The basic assumption, in economic terms, is that the chance of a certain proportionate growth or shrinkage is independent of the size already reached—the law of proportionate effect. This law was proposed by J. C. Kapteyn, by Francis Galton, and, later, by Gibrat (1931).

Let size (of towns, firms, incomes) at time  $t$  be denoted by  $Y(t)$ , and let  $\epsilon(t)$  represent a random variable with a certain distribution. We have

$$Y(t) - Y(t-1) = \epsilon(t)Y(t-1),$$

$$Y(t) = (1 + \epsilon(t))Y(t-1)$$

$$= Y(0)(1 + \epsilon(1)) \cdots (1 + \epsilon(t)),$$

where  $Y(0)$  is size at time 0, the initial period. For small time intervals the logarithm of size can be represented as the sum of independent random variables and an initial size which will become negligible as  $t$  grows:

$$\log Y(t) = \log Y(0) + \epsilon(1) + \epsilon(2) \cdots + \epsilon(t).$$

If the random variables  $\epsilon$  are identically distributed with mean  $m$  and variance  $\sigma^2$ , the distribution of  $\log Y(t)$  will be normal with mean  $mt$  and variance  $\sigma^2 t$ .

This random walk corresponds to the process of diffusion in physics which is illustrated by the so-called Brownian movement of particles of dust put into a drop of liquid. Since it implies an ever growing variance, the idea of Gibrat is not itself enough to provide an explanation for a stable distribution. There must be a stabilizing influence to offset the tendency of the variance to increase; indeed, a distinguishing feature of the various theories presently to be reviewed lies in the kind of stabilizer they introduce to offset the diffusion. Two interesting cases may be noted here. One possibility is to modify the law of proportionate effect and assume that the chances of growth decline as size increases. This approach has been taken by Kalecki (1945), who assumes a negative correlation between the size and the jump and obtains a Gibrat law with constant variance. Another possibility is to combine the diffusion process of the random walk with a steady inflow of new, small units (firms, cities, incomes). Some units may continue indefinitely to increase in size, but

their weight will be offset by that of a continuous stream of many new, small entrants, so that both the mean and the variance of the distribution will remain constant. This approach, which leads to the Pareto law, has been taken by Simon (1955).

**Review of various models.** Descriptions of various models will illustrate the methods employed. Models differ with regard to the distribution law explained, the field of application (towns, incomes, etc.), and the type of stochastic process used.

**Champernowne's model.** Champernowne (1953) presents a model that explains the Pareto law for the size distribution of incomes. The stochastic process employed is the so-called Markov chain [see MARKOV CHAINS]. The model is based on a matrix of probabilities of transition from one income class to another in a certain interval of time, say a year. The rows are the income classes of one year, the columns the income classes of the next year. The income classes are chosen in such a way that they are equal on the logarithmic scale (for example, incomes from 1 to 10, from 10 to 100, etc.). The probability of a jump from one income class to the next income class in the course of a year is assumed to be independent of the income from which the jump is made (the law of proportionate effect). The number of income earners is constant.

The number of income earners in income class  $s$  is then determined as follows. The number of incomes in class  $s$  at time  $t + 1$  is

$$f(s, t + 1) = \sum_{u=-n}^1 f(s - u, t)p(u),$$

where  $s$ ,  $u$ , and  $t$  take on integer values,  $p(u)$  is the probability of a jump over  $u$  intervals (i.e., the transition probability), and the size of the jump is constrained to the range  $+1, -n$ . In the steady state equilibrium reached after a sufficiently long time has passed, the action of the transition matrix leaves the distribution unchanged. We then have

$$f(s) = \sum_{u=-n}^1 f(s - u)p(u), \quad s > 0,$$

as  $t \rightarrow \infty$ . This difference equation is solved by putting  $f(s) = z^s$ . The characteristic equation

$$g(z) = \sum_{u=-n}^1 z^{1-u}p(u) - z = 0$$

has two positive real roots, one of which is unity. To assure that the other root will be between 0 and 1, Champernowne introduces the following stability condition:

$$g'(1) = - \sum_{u=-n}^1 up(u) > 0.$$

The relevant solution is  $f(s) = b^s$ ,  $0 < b < 1$ , which gives the number of incomes in income class  $s$ . If the lower bound of this class is the log of the income  $Y_s$ , then the probability of an income exceeding  $Y_s$  is given by

$$\log P(Y_s) = s \log b.$$

Since  $s$  is determined by

$$\log Y_s = sh + \log Y_{\min},$$

where  $h$  is the class interval and  $Y_{\min}$  is the lower boundary of the lowest income class, it follows that

$$\log P(Y_s) = \gamma - \alpha \log Y_s,$$

where the parameters  $\gamma$  and  $\alpha$  are determined by  $b$ ,  $h$ , and  $Y_{\min}$ . This is the Pareto law with Pareto coefficient  $\alpha$ .

Champernowne's stability condition implies that the mathematical expectation of a change in income is negative. This counteracts the diffusion. How can the stability condition be justified on economic grounds? It may be connected with the fact that in this model every income earner who drops out is replaced by a new income earner. Since, in practice, young people have on the average lower and more uniform incomes than old people, the replacement of old income earners by young ones usually means a drop in income. Thus, Champernowne's stability condition, as far as its economic basis is concerned, is very similar to the entry of new, small units that act as a stabilizer in Simon's model.

**Rutherford's model.** Rutherford's model (1955) leads, in his opinion, to the Gibrat law for the size distribution of incomes. Newly entering income earners, assumed to be log-normally distributed at the start, are subject to a random walk and thus to increasing variance during their lifetimes. The process of birth and death of income earners, which is explicitly introduced into the model, acts as the stabilizer.

The distribution of total income is obtained by summing the distributions for all age cohorts that contribute survivors. Rutherford's method is to derive the moments of the distribution by integration over time of the moments for the entrance groups. The distribution is built up "synthetically" from the moments, as it were. In the absence of an analytical solution with a definite distribution law, some disagreement remains about the result.

**Simon's model.** In Simon's model (1955), which leads to what he calls the Yule distribution, the aggregate growth of firms, cities, or incomes is given a priori. The stochastic process apportions this given increment to various units according to

certain rules, which are weakened forms of the law of proportionate effect and rules of new entry. As a consequence of this procedure, there is no possibility of shrinkage of individual units. The given aggregate emphasizes the interdependence of fortunes of different firms (the gain of one is the loss of another)—a point that is neglected in other models, such as that of Steindl (1965). On the other hand, the aggregate is, in reality, not given; it is not independent of the action of the firms, which may increase their total market by advertising, product innovation, and so on.

The process of apportionment may be described as follows. We may conveniently think of populations of cities, so that  $f(n, N)$  is the frequency of cities with  $n$  inhabitants in a total urban population of  $N$ ; to be realistic, we shall assume that a city exceeds a certain minimum number of inhabitants;  $n$  will measure the excess over this minimum, and  $N$  will correspondingly be the sum of these excess populations. An additional urban inhabitant is allocated to a new city with a probability  $\alpha$  and to an existing city, of any size class, with a probability proportionate to the number of (excess) inhabitants in that size class. Then,

$$\begin{aligned} f(n, N+1) - f(n, N) \\ &= \frac{1-\alpha}{N} [(n-1)f(n-1, N) - nf(n, N)], \\ f(1, N+1) - f(1, N) \\ &= \alpha - \frac{1-\alpha}{N} f(1, N). \end{aligned}$$

We assume that there is a steady state solution in which the frequencies of all classes of cities change in the same proportion, that is, in which

$$\frac{f(n, N+1)}{f(n, N)} = \frac{N+1}{N}, \quad \text{for all } n.$$

Using this relation and defining a relative frequency of cities as  $f(n) = f(n, N)/(\alpha N)$ , we obtain from the above equations

$$\begin{aligned} f(n) &= f(n-1) \frac{(1-\alpha)(n-1)}{1 + (1-\alpha)n} \\ f(1) &= \frac{1}{2-\alpha}; \end{aligned}$$

or, setting  $1/(1-\alpha) = \rho$ ,

$$\begin{aligned} f(n) &= \frac{(n-1)(n-2) \cdots 2 \cdot 1}{(n+\rho)(n+\rho-1) \cdots (2+\rho)} f(1) \\ &= \frac{\Gamma(n)\Gamma(\rho+2)}{\Gamma(n+\rho+1)} f(1). \end{aligned}$$

This expression is the Yule distribution. Using a property of the  $\Gamma$ -function, it can be shown that the

Yule distribution asymptotically approaches the Pareto law for large values of  $n$ , that is,  $f(n) \rightarrow n^{-\rho-1}f(1)\Gamma(\rho+2)$  as  $n \rightarrow \infty$ .

This model is applicable to cases in which size is measured by a stock, for example, number of employees of a firm. Simon provides an alternative interpretation of it that applies to flows, such as income and turnover of firms. For example, the total flow of income is given, and each dollar is apportioned to existing and new income earners according to the rules given above.

Using simulation techniques, Ijiri and Simon (1964) show that the pattern of the Yule distribution persists if serial correlation of the growth of individual firms in different periods is assumed. This finding is important because, in reality, growth is often affected by "constitutional" factors, such as financial resources and research done in the past.

*The model of Wold and Whittle.* Wold and Whittle (1957) present a model of the size distribution of wealth in which stability is provided by the turnover of generations, as in Rutherford's model. On the death of a wealth owner, his fortune is divided among his heirs (in equal parts, as a simplification). The diffusion effect is provided by the growth of wealth of living proprietors, which proceeds deterministically at compound interest. The model is shown to lead to a Pareto distribution, the Pareto coefficient depending on the number of heirs to an estate and the ratio of the growth rate of capital to the mortality rate of the wealth owners.

*Steindl's models.* Steindl's models (1965, chapters 2, 3) are designed to explain the size distribution of firms, but they can equally well be applied to the size distribution of cities. The distribution laws obtained are, for large sizes, identical with the Pareto law. Like Rutherford's model, Steindl's models rest on a combination of two stochastic processes. One is a birth-and-death process of the population of cities or firms; the other is a stochastic process of the growth of the city or firm itself.

The way in which the interplay of these two processes brings about the Pareto law can be explained in elementary terms. We start with the size distribution of cities. The number of cities can be explained by a birth process, if we assume that cities do not die. Let us assume that new cities are appearing at a constant rate,  $\epsilon$ , the birth rate of cities. The number of cities increases exponentially, and the age distribution of cities at a given moment of time is

$$(1) \quad R(t) = R(0)e^{-\epsilon t}, \quad \epsilon > 0,$$

where  $t$  is age and  $R(t)$  is the number of cities with age in excess of  $t$ ; in other words,  $R(t)$  is the rank of the town aged  $t + dt$ , and  $R(0)$  is the total number of towns existing at the moment of time considered. The size of the city—its number of inhabitants—increases, on the average, with age. If the rate of births plus immigration,  $\lambda$ , and of deaths plus emigration,  $\mu$ , are constant, we obtain an exponential growth function for the size of the city:

$$(2) \quad n(t) = e^{(\lambda - \mu)t}, \quad \lambda > \mu.$$

Eliminating  $t$  between eqs. (1) and (2), we get

$$(3) \quad \ln R = -\frac{\epsilon}{\lambda - \mu} \ln n + \ln R(0).$$

This is the Pareto law (if  $\epsilon/(\lambda - \mu) > 1$ ), and the Pareto coefficient is seen to be the ratio of the growth rate of the number of cities to the growth rate of a city.

This demonstration, which on the face of it is deterministic in character, can be supplemented by a graphical illustration in which the stochastic features are included. In Figure 1 the distribution of cities according to age is plotted in the vertical ( $\ln R, t$ ) plane. The abscissa shows the age of the city, and the ordinate shows the log of the rank of the city. Each city is thus represented by a dot, and the regression line fitted to these points represents relation (1). In the horizontal ( $t, \ln n$ ) plane, we show the exponential growth of cities with age, as in relation (2). Again each city may be represented by a dot showing age and size. The scatter diagram in the horizontal plane may be regarded as a stochastic transformation of the time variable into the size variable. If the size of each city has been found on the scatter diagram, the cities can be reordered according to size; we then obtain, in the third ( $\ln R, \ln n$ ) plane, the transformed relation (3) between the number of cities (rank) and the size of a city.

If firms are studied, we must take into account the death of firms. We might assume that a firm dies when it ceases to have customers. We can imagine that the age distribution in plane 1 of Figure 1 includes the dead firms; they are automatically eliminated in the transformation to size, being transferred to the size class below one. In the exponential relation (1),  $\epsilon$  must now represent the net rate of growth of the number of firms if the birth of firms is assumed to be a constant ratio of the population.

Figure 1 illustrates how the evolution in time of the number of firms (cities) is mapped onto the cross section of sizes. This process may be compared to sedimentation in geology, where a

historical development is revealed in a cross section of the layers. We can also see how irregularities in the evolution over time will affect the size distribution. If an exceptional spurt of births of new firms occurs at one point of time (after a war, for example), the regression line in plane 1 will be broken and its upper part shifted upward in a parallel fashion. The same thing will happen to the transformed distribution in plane 3.

Figure 1

The complete model for firms may be described as follows. The size of a firm is measured by the number of customers attached to it. This is governed by a birth-and-death process. Let us denote by  $o(\Delta t)$  a magnitude that is small in comparison with  $\Delta t$ . There is a chance  $\lambda \Delta t + o(\Delta t)$  of a customer's being acquired and a chance  $\mu \Delta t + o(\Delta t)$  of a customer's being lost in a short period of time,  $\Delta t$ ; multiple births and deaths have a chance of  $o(\Delta t)$ . The probability that a firm has  $n$  or more than  $n$  customers is given by

$$P(n) = \int_0^\infty P(n, t) \tau(t) dt,$$

where  $P(n, t)$  is the probability that a firm of age  $t$  has  $n$  or more than  $n$  customers. The term  $\tau(t)$  is the density of the age distribution of firms, including dead firms; for large  $t$  it is the steady state of a renewal process and is given by  $\tau(t) = ce^{-\epsilon t}$ , where  $\epsilon$  is the net rate of growth of the firm population and  $c$  is a constant. The number of firms with less than one customer,  $P(0, t) - P(1, t)$ , equals the dead firms. The value of  $P(n, t)$  is obtained as the solution of a birth-and-death process for the customers of a firm:

$$P(n, t) = \left(1 - \frac{\mu}{\lambda}\right) \frac{(1 - \alpha')^{n-1}}{(1 - \alpha')^n}, \quad n = 1, 2, \dots,$$

where  $\alpha = e^{-(\lambda - \mu)t}$ ,  $\alpha' = (\mu/\lambda)e^{-(\lambda - \mu)t}$ , and  $\lambda > \mu$ . This expression can be expanded in series and in-

serted in the above integral; this yields, integrating term by term,

$$P(n) = C \sum_{\nu=0}^{\infty} \sum_{k=0}^{n-1} \frac{\left(\frac{-\mu}{\lambda}\right)^{\nu+k} \binom{-n}{\nu} \binom{n-1}{k}}{\nu+k+\omega}$$

$$= C \sum_{\nu=0}^{\infty} \left(-\mu/\lambda\right)^{\nu} \binom{-n}{\nu} B(n, \omega + \nu),$$

where  $\omega = \epsilon/(\lambda - \mu) > 0$  and  $B(n, \omega + \nu)$  is the Beta integral. Hence,

$$P(n) = C \sum_{\nu=0}^{\infty} \left(\frac{\mu}{\lambda}\right)^{\nu} \frac{1}{\nu B(n, \nu)} B(n, \omega + \nu).$$

If  $\mu/\lambda < 1$ , we can neglect the terms with  $\nu$  above a certain value. Thus, if  $n \rightarrow \infty$  and  $\nu$  has a moderate value, we can use the approximations

$$B(n, \omega + \nu) \approx n^{-\omega-\nu} \Gamma(\omega + \nu),$$

$$B(n, \nu) \approx n^{-\nu} \Gamma(\nu);$$

therefore, as  $n \rightarrow \infty$ ,

$$P(n) \rightarrow C'n^{-\omega}.$$

The following features of the solution may be remarked: Since the approximation depends on the value of  $\mu/\lambda$ , which is the mortality of firms of high age, the smaller the mortality of firms, the greater will be the proportion of the distribution that conforms to Pareto's law. The mean of the distribution will be finite if  $\omega > 1$ . This is important in connection with disequilibria, which can arise through changes in  $\lambda$ ,  $\mu$ , and  $\epsilon$ . It can be shown that the Pareto solution applies to the growing firm ( $\lambda > \mu$ , the above case) and, in a modified form, to the shrinking firm ( $\lambda < \mu$ ); but it does not obtain for the stationary firm ( $\lambda = \mu$ ).

The above solution for the distribution according to customers can be shown to be valid also for the distribution according to sales, if firms grow mainly by acquiring more customers and not by getting bigger customers. This is often true in retail trade but not in manufacturing. An alternative model assumes the other extreme—that firms grow only by getting bigger orders. This model is based on the theory of collective risk. The capital of the firm, a continuous variable, is subject to sudden jumps at the instant when orders are executed and to a continuing drain of costs, which is represented deterministically by an exponential decline. The steady state solution obtained from this process is, for large values of capital, identical with the Pareto law; for moderate values, the distribution has a mode and represents, albeit with some complications, a modification of the "first law of Laplace," which was proposed by Fréchet (1939) for income distributions.

**Size as a vector.** It would be natural to measure the size of a firm by a vector, including employment, output, capital, etc., and apply the steady state concept to the joint distribution of several variables. Regression and correlation coefficients obtained in a cross section could then be regarded, like the Pareto coefficient, as characteristics of the steady state. It may be guessed that the growth of the number of firms will have an influence on these parameters as well.

Practically no work has been done in this direction, but it is the only way to clear up the meaning of cross-section data and their relation to time series data and to the theoretical parameters of the underlying stochastic process. The situation in economics is totally unlike that in physics, where the processes are stationary and the ergodic law establishes the identity of time and phase averages. (Only the cosmogony of F. Hoyle, in which the continuous creation of matter offsets the expansion of the universe to establish a steady state of the cosmos, offers a parallel to the growth processes considered above.) The surprise expressed at one time at the difference in estimates of income elasticities from cross-section data and from time series data appears naive in this light because we could only expect them to be equal if the processes generating households, incomes, and consumption were stationary.

But the population of households or the population of firms is not stationary. A cross section of firms shows the growth path of the firm through its different stages of evolution; but the number of firms of a given age depends on the past growth of the total number of firms, and this may influence the regression coefficient. Moreover, the growth path is not unique, because there are several processes superimposed upon one another (growth paths depending on age of firm, age of equipment, age of the management, etc.). For example, the short-run and long-run cost curves are inevitably mixed up in a cross section of firms. [See Cross-section Analysis.]

**How much "stability" and why.** The starting point of the theories here reviewed is the stability of distributions, but stability must not be taken literally. The distributions do change in time, but the change is usually slow. The tail of the distribution of firms or, to a lesser extent, of wealth is composed of very old units, and time must pass before it can be affected by, for example, a change in new entry rates or in growth rates of firms. Thus, the reason for the quasi stability of distributions is that the stock of firms, etc., revolves only slowly. Indirectly this also accounts for the quasi stability of the distribution of incomes, because in-

come is largely determined by wealth or its equivalent in the form of education. An even more enduring influence on the income distribution is the differentiation of skills and professions, which evolves slowly, as a secular process.

The explanations advanced in this article do not exclude the possibility that distribution patterns may change abruptly—for example, as a consequence of taxation, in the case of net incomes; or as a consequence of a big merger movement, in the case of firms.

## SKILL, ACQUISITION OF

See under LEARNING.

## SKIN SENSES AND KINESTHESIS

The skin senses and kinesthesia (muscle and movement senses) present a difficult problem in sensory physiology—the problem of how information about several energies of the external world are signaled to the brain. Skin receptors are sensitive to thermal and mechanical stimulation, and mechan-

ical stimulation is detected in a variety of ways both by sense organs in cutaneous structures and deep, internal structures such as muscles, tendons, and joints. In varying degrees, deep receptors also detect the state of the tissues or the position of the body and limbs in space.

At one time, it was thought that a single skin sense—so-called common sensibility—detected touch, pressure, warmth, cold, and pain. Beginning in the late nineteenth century, the concept of separate sensory modalities developed, based on the presumed existence of histologically distinct sets of sense organs for each cutaneous sense, of some separation of pathways in the spinal cord, and of specific endings in the cerebral cortex (see Boring 1942). The one concrete experimental datum was a spotlike, or punctiform, distribution of sensitivity, determined by exploring the skin millimeter by millimeter with different energies and finding different psychological responses—touch, warmth, cold—from different spots. This punctiform sensitivity seemed to demand specific anatomical endings. The histological specificity—various encapsulations of the neural terminals themselves—described by anatomists seemed to provide a structural correlate for several psychological and physiological findings. However, the search for a histologically distinctive receptor beneath a sensitive spot proved elusive.

The minimum demanded is that this receptor be a sense organ that responds differentially or differently to various forms of energy. The traditional view is that a sense organ responds differentially to one energy or to one band of an energy spectrum (e.g., warmth and cold or frequencies of light waves) and analyzes an object in contact with the skin in terms of this energy or band of energy. Such a filter function is traditionally expressed by the concept of *adequate stimulus* or, better worded, *differential sensitivity*. Like all filters, the sense organ has a low *threshold* for one form of energy or for one band of frequencies within a given form of energy.

An alternative view holds that sense organs are much alike in their range of sensitivity to a variety of energies but respond differently in some way ("frequency" or "pattern") to each energy, leaving the central nervous system to interpret the different responses and recognize the different energies (Weddell 1961). These points of view are caught in a crosscurrent of contradictory experimental findings.

## Receptors

Since the mid-1950s, the point of view that receptors are alike in their range of sensitivities and

that discrimination of sensations is a joint function of receptor responses and processes in the central nervous system has received considerable support from evidence that there is little morphological differentiation of receptors in hairy skin, although hairy skin indisputably signals different modalities of sensation. While hairless skin (lips, fingertips, etc.) does contain specialized endings, it became gradually accepted, on the basis of Weddell's work (1961), that only two types of endings exist in hairy skin: fibers originating about the roots of hairs and fine, beaded, unmyelinated, or so-called free, nerve endings. Because the same modalities of sensation are experienced from stimulation of hairy and hairless skin, specificity or band-pass characteristics cannot then be attributed to any capsules or discs that are associated with the specialized nerve terminals in hairless skin. Anatomical studies have not disproved the functional specificity of the terminations; whatever specificity exists must, however, be on a subcellular or molecular basis, not visible with the light microscope and conventional stains.

Actually, in slight contradiction of Weddell's broad generalization, there are several types of hair receptors having somewhat different discharge properties, but all are receptors for mechanical stimulation (mechanoreceptors). Also, the conspicuously encapsulated organ—the Pacinian corpuscle—is found in the dermis and subcutaneous tissues. Iggo and Muir (1963) have discovered a morphologically specialized end organ that consists of a thickened epidermis covering several Merkel-type corpuscles, into which penetrate branches of a single thick myelinated axon. This spotlike receptor is also a mechanoreceptor. Deep in the skin and in muscles and tendons, there are encapsulated or otherwise specialized sense organs. Knowledge of sense-organ morphology is in a curious state because certain "classical" formations are now considered artifacts, but at least one *new* type has been discovered.

Another plausible morphologically based generalization, now proved to be invalid, is that all free nerve endings are pain receptors and that their lack of capsule or morphological complexity accounts for the wide variety of energies that can elicit cutaneous pain—namely, mechanical, heat, cold, and chemical stimulation. Passing from the skin to the spinal cord are numerous small axons, measuring about  $1\mu$  in diameter, which conduct nerve impulses at about 1 meter per second and are termed unmyelinated. (Under the light microscopes they appear to lack a surrounding sheath of white fatty material, myelin; electronmicroscopy reveals a thin myelin sheath.) These fibers, termed

C-fibers, conduct impulses which result in painful sensation; so do the smallest fibers with optically visible myelin sheaths. These fibers, called  $\delta$ -fibers, conduct impulses at a considerably faster rate, about 6 meters per second. Because of this double system of fibers, pain can be appreciated, in certain circumstances, as two pulses: "fast" pain and "slow" pain.

It has recently been learned that touch and thermal stimuli excite nerve impulses at intensities of stimulation far below that required to elicit pain. In fact, a large number of the C-fibers can be recruited into responding before the level of stimulation required to elicit pain is reached. Thus, it can no longer be held that the fine unmyelinated axons are concerned exclusively with conducting the impulses that arise within high-threshold end organs and that their central effect results only in the experience of pain. [See PAIN.]

Until recently, knowledge of C-fiber function has been largely inferential, because the small action potentials produced by them have been difficult to record. Douglas, Ritchie, and Straub (1960) caused impulses in the large-diameter, low-threshold axons to collide and, thus, eliminate themselves, leaving only the C-fiber impulses to reach the recording electrode. Activation of C-fibers did not require the strong mechanical or thermal stimulation that elicits pain sensation. In fact, a fall in skin temperature of  $10^\circ\text{C}$ ., less than is required to elicit a painful sensation, activated three-quarters of the C-fibers. Clearly, the C-fibers cannot be concerned solely with pain sensation. This general conclusion is supported by the more direct, classical procedure of "cutting down" a nerve until impulses in only one axon are recorded. This procedure, accomplished by Iggo (1959), showed that C-fibers do respond to more than one form of energy and with weaker stimulation than that required to elicit pain. In fact, they respond to stimuli not much stronger than those required to stimulate the specifically sensitive endings connected with large unmyelinated axons of sensory neurons. C-fiber discharges to a temperature drop as little as  $0.3^\circ\text{C}$ . have been recorded.

Recording from a single axon has been accomplished in man (Hensel & Boman 1960). Receptors connecting with myelinated fibers respond weakly to cold stimulation and strongly to mechanical stimulation. They tend to fire "spontaneously" at natural skin temperature in the absence of known mechanical stimulation.

The one epidermal receptor which is highly structured and is served by a large unmyelinated axon—the touch spot receptor of Iggo and Muir (1963)—discharges in response to cooling. This

receptor is slow in adapting. The muscle spindle, which also adapts slowly, is also sensitive to cooling, but the very rapidly adapting Pacinian corpuscle is not. Iggo (1965) believes that the effect of cooling is a general property of mechanoreceptors which takes time to develop. Postulation of a multispecific ending is not necessary. Whatever the cause, the nervous system has the problem of "decoding" the discharge from such end organs.

In contrast, an ending responding specifically to heat has been discovered. This ending is termed a heat receptor, since it does not respond to strong mechanical and cold stimulation.

**Protopathic and epicritic sensibility.** Since the primitive, fine unmyelinated fibers cannot be associated exclusively with the most primitive and least discriminative sense, the pain modality, and since some myelinated fibers have endings which are thermally, as well as mechanically, sensitive, it is inevitable that thinking should return (Poggio & Mountcastle 1960) to the all but discarded theory of protopathic and epicritic sensibilities, proposed by Henry Head (see Head et al. 1920). The protopathic system was postulated to be sensitive only to extremes of temperature and capable only of gross discriminations, whereas the epicritic was sensitive to light touch and fine gradations of warmth and cold and capable of fine discriminations of pressure and weight. In a sense, a central neural substrate has been furnished by the research just described, assuming always that the afferent neurons described transmit impulses to the brain. Before further consideration of this assumption in the discussion of the spinal pathways of sensation, it should be noted that Head's theory is criticized because quantitative explanations can be given for phenomena which he felt had to be explained in terms of qualitatively different neural mechanisms.

**Deep sensitivity.** Sensory information coming over the deep branches of peripheral nerves is termed deep sensitivity or, specifically, muscle, tendon, and joint sensitivity. Sherrington (1906) introduced the term "proprioception" ("self-sensitivity"), in contrast to "exteroception" ("giving knowledge of the outside world"). "Kinesthesia," or "sense of movement," is favored by some (Rose & Mountcastle 1959), in the belief that the impulses reaching the cerebral cortex come only from joints rather than from muscle and are, therefore, particularly, although not exclusively, excited by movement. The deep receptors lie also in muscle; they record not only active but passive movement and record the posture or position of a limb in space (in neurological jargon, "position sense"). [See SHERRINGTON.]

**Intensity, affect, and place.** So far, this discussion has dealt with the *kind* of stimulus energy that is signaled. The phenomenological counterpart is the *quality* of the sensation, the differences in experience which cause us to give sensations different names such as warmth, cold, touch, or pressure. Sensation has three other aspects which are intriguing neurophysiological puzzles and are of great medical importance: The first of these is *intensity* of stimulation. The second is *affect*, the aspect of a sensory experience which causes us to describe it as pleasant or unpleasant. This phase of sensation blends into the problems of motivation and emotion. The third is *place*, or the spatial-discrimination aspects of cutaneous sensibility.

Intensity is peripherally coded in the frequency of discharge or, perhaps more accurately, in the quantity of impulses—that is, frequency times number of responding fibers. It is no longer likely that affect can be fiber-coded in the periphery—for example, that pain can be identified with C-fibers as a group. The problem becomes one of the destination of the impulse within the brain.

Spatial discrimination involves the ability to locate on the skin surface the point of stimulation (topognosis) and an allied function, so-called two-point discrimination, measured as the smallest distance at which two points applied to the skin are sensed as two rather than one—a function comparable to visual acuity. Errors of localization and fineness of point discrimination are small on the skin surfaces used to explore objects—fingertips, lips, and tongue—and poorly developed on the back and proximal segments of the limbs. Acuity is related to the density of the receptors and to the number of sensory axons supplying the region.

In spatial discriminations, cutaneous and deep receptors combine to provide information about the form of an object palpated and, with the sensations of temperature, weight, etc., enable us to recognize common objects by palpation (stereognosis). Although it is customary to speak loosely of these as sensory processes, technically they are perceptions and judgments. A considerable evolution of the brain has been required to add to the mere recognition of touch, cold, warmth, or pain the abilities to discriminate their fine degrees of intensity, to locate the point on the skin stimulated, and to appreciate the spatial aspects of objects. [For a detailed discussion of intensity and the spatial and affective aspects of sensation, see Ruch & Patton 1965; see also PERCEPTION, article on DEPTH PERCEPTION.]

**Convergence of axons.** Another threat to the concept of specific receptors connected by separate

pathways to the cerebral cortex is the discovery that afferent axons that are apparently specific in the periphery for different kinds of energy converge on the same second-order neuron on the spinal cord. This occurs with axons that terminate on neurons in the posterior horn but not for all second-order neurons on which the posterior-column fibers terminate. Specificity (filtering) and the resulting information would be lost if the transmitting channel had a wide-band pass, unless the streams of impulses from the two narrow-band-pass sense organs were coded differently in the second and subsequent neurons. It has not yet been demonstrated that the single secondary neuron in which the nerve impulses are detected gives rise to ascending sensory fibers. However, similar nonspecific behavior is found in some third-order neurons and some cortical neurons, as will be discussed below.

The simple alternative to specific sensory end organs is frequency coding. A sense organ may fire at one rate when stimulated by touch and at another rate when stimulated by pressure. Alternatively, two specific end organs may, through their axons, fire a second-order neuron at two different rates. The difficulty with either concept is that the frequency code is, so to speak, needed to signal the intensity of a stimulus, as can be seen when the intimate nature of sense-organ excitation is examined.

**Receptor potentials and nerve impulses.** The mechanoreceptor is a transducer that converts non-electrical energy into an electrochemical phenomenon, the generator, or receptor, potential. This potential, in turn, sets up action potentials in the parent axon which are brief, self-propagating, and independent, in size and velocity, of the strength of the stimulus or of the generator potential. By contrast, the magnitude of the generator potential is related in logarithmic proportion to the magnitude of the physical stimulus. Further, the generator potential is stationary, decreasing rapidly with distance along the axon; in response to a sustained stimulus, it tends to be prolonged, although not usually sustained at its initial level. The propagated all-or-none action potentials (nerve impulses) are always intermittent. When the generator potential reaches a certain value (a threshold), the axon is discharged and cannot again be fired until certain changes underlying self-propagation are reversed. [See NERVOUS SYSTEM, especially the articles on STRUCTURE AND FUNCTION OF THE BRAIN and ELECTROENCEPHALOGRAPHY.]

In some receptors, the generator potential dies out so rapidly that only one or two impulses are

set up. Such phasic receptors can signal intensity by their proximity to the stimulus or by differing axon thresholds, which permit stronger and stronger stimuli to involve more and more axons. Such a recruitment will, through convergence at the second-order neuron, mean that more impulses per second reach the brain.

In the tonic type of sensory neuron, the generator potential persists as long as there is a stimulus, but as mentioned, the potential tends to diminish from its initial level to an approximate plateau. So long as this potential exceeds axon threshold, impulses will continue to be generated. However, as the generator potential diminishes, so does the rate of discharge. Since continuance of a stimulus is accompanied by a psychological decrease in intensity (adaptation), the declining frequency of sensory-axon discharge is consistent with the supposition that frequency is the way in which stimulus intensity is coded. More directly, if different plateau levels of the generator potential are induced by different magnitudes of stimulation, the frequency of discharge is *directly and linearly* proportional to the generator potential. The over-all logarithmic relationship between intensity of stimulus and frequency of nerve impulses, characteristic of many receptors, lies in the logarithmic relationship between the magnitude of the physical stimulus and the generator potential. From an engineering point of view, sense organs are poor transducers in respect to linearity, although good in respect to reducing a wide range of intensities to the somewhat limited frequency capacity of nerve axons (600 pulses per second being the upper limit).

### Central sensory processes

The classical somatosensory (skin senses and kinesthesia) pathway in man, monkeys, and apes is made up of systems originating in both the posterior and anterolateral columns of the spinal cord. All sensory pathways are synaptically interrupted. Anterolateral-column pathways first synapse near the point of entry into the spinal cord. Posterior-column pathways synapse for the first time in the lowest region of the brain stem, the medulla.

In both pathways, crossing occurs after the first synapse, so that the left side of the brain is concerned with the right side of the body, as is true of vision and motor function. In man and monkey, the second-order neurons of both sensory pathways synapse in the ventroposterior portion of the thalamus with third-order neurons which project to the cortical areas. The classical somatosensory pathway is conducted by the medial and spinothalamic lemnisci to the posterolateral point of the ventral

nucleus, where it ends in a topographically organized fashion, so that the body surface is projected upon this nucleus (for the detail of this pathway, see Ruch & Patton 1965).

Some pathways, especially those of the anterolateral column, have more than three neurons. In the cat, for example, the *spinothalamic tract*, in the literal sense of the term ("one neuron from cord to thalamus"), does not exist; all of the second-order myelinated fibers synapse before they reach the thalamus. This distinction can be conveyed by speaking of spinothalamic tracts and spinothalamic chains or systems. With the present techniques for studying experimental degeneration in myelinated fibers by staining the axon rather than the disintegrating myelin sheath (and, of course, unmyelinated fibers), the extensiveness of the multisynaptic pathways is just becoming appreciated. In brief, at various levels of the brain stem, many ascending axons give off branches to or terminate on neurons in the central gray matter and reticular substance (a deep-lying meshwork of fibers containing clusters of cell bodies). From these levels, neuron chains proceed to certain thalamic areas which in turn connect with the cerebral cortex. Since the C-fiber system is stimulated peripherally by other than noxious stimuli, the multineuron, fine-fiber ascending system is potentially concerned with all forms of cutaneous sensation.

Two questions can be asked concerning the transmission of sensory information in the spinal cord through the thalamus to the cerebral cortex: First, to what degree is the energy specificity of the sense organ preserved at the first synaptic junction? Second, to what degree do the second-order and third-order neurons receive impulses from a restricted area of the skin? The answer to the latter is indicative of, but not a measure of, the preservation of locus of stimulus in ascending pathways.

Wall (1961), in recording from single second-order neurons of the posterior horn (not to be confused with the posterior column) of the spinal cord, has discovered that they tend to be fired by a variety of stimuli. The axons of these neurons ascend in the anterolateral columns, and the impression is gained that in some anterolateral systems the degree of fiber coding attained in the periphery is largely sacrificed at the first synapse. The kind of stimulation must, therefore, be coded in some other dimension of the stream of afferent impulses. It should be mentioned that reflex connections, as well as ascending axons, originate in the posterior horn and that many anterolateral and posterolateral ascending pathways beside the spinothalamic tract have cells of origin in this region.

It seems, then, that in some ascending pathways, specificity in relation to stimulus energy has been lost in the transfer to secondary axons; either the information itself is lost or else it is coded in some other fashion. Temporal patterning is suggested as the means of coding (Wall 1961).

**Posterior-column pathways.** The behavior of the sensory pathways which ascend the posterior columns of the spinal cord without synapsing and without crossing until they reach the medulla is quite different. In the medulla, the second-order neurons, after crossing, give rise to the medial lemniscus, which ascends the brain stem to the thalamus. The transmission of information which conveys the site of stimulation on the skin is considered by most neurophysiologists to be a product of a topographical organization of axons within ascending pathways that is preserved throughout the thalamic relay nuclei and the thalamocortical projections. The result is a kind of "isomorphism" between the peripheral array of skin receptors and the array of neurons making up the cerebral cortex. This organization must not be thought of in terms so crude as a single receptor being connected with a single cortical cell, an adjacent receptor with an adjacent cortical cell, etc. Such "structural canalization" of pathways seems to be almost deliberately avoided, even in systems—such as the visual—which have a high degree of acuity and spatial discrimination.

**Receptive fields.** There is much interdigitation of free nerve endings in the skin which would seem unnecessary unless some biological value is attained. On the other hand, the number of channels and the degree of their "insulation" from each other (i.e., lack of convergence) at synaptic levels are highest for the points of greatest acuity and spatial discrimination (e.g., the fovea of the retina and the tips of the fingers). One index of topographical organization and potential acuity is the "receptive field." The receptive field of a single axon or cell body is that area of skin from which the unit can be discharged (or, in the case of the eye, the area of the visual field in which the unit can be discharged or inhibited). Thus, each peripheral axon, secondary neuron, and cortical cell has a receptive field.

The receptive fields of the second-order neurons of the posterior-column and the anterolateral-column pathways contrast sharply; the former are measured in millimeters, and the latter, in centimeters. Although large, the receptive fields of second-order neurons on the anterolateral pathways are not splotchy but homogeneous and are often round or elliptical, indicating that many peripheral

axons with adjacent or overlapping fields on the skin have converged in an orderly fashion.

Another finding, which seems to pertain to even the posterior column system, is that receptive fields are larger at the cortical level than at the level of the second-order neuron. This rule also holds in the visual system, where form appreciation can be seen in the divergence or widening of the channel (Hubel & Wiesel 1965). In the skin senses, a similar analysis has yet to be made empirically, although it has been subject to speculation.

The anterolateral-column pathways are a phylogenetically primitive system that receives impulses from unmyelinated and fine myelinated fibers; that conducts impulses which inform the brain of the state of the skin and tissues and, to some degree, of the ambient environment and objects (e.g., their warmth or coldness) but that may report poorly on spatial aspects of the stimulus. Geometrical patterns of warmed or cooled skin induced by radiant energy are very poorly discriminated. It may be important to know that a hand or an arm is cold or painful but not that one millimeter of skin is cold and the next warm. In contrast, the posterior-column pathways have been considered to convey knowledge of the objects forming the external world, the position of the body and the limbs in space, and the accurate locus of stimulation (Ruch & Patton 1965).

In this generalization, the reservation should be made that the anterolateral system of man and other primates is not the primitive system of fibers seen in lower forms, but it does reach the thalamus and conveys some limited knowledge of the world. Because the posterior columns are rarely selectively interrupted by trauma or tumor, the residual capacity of the spinothalamic and other lateral, anterolateral, and ventral ascending pathways is poorly understood. From experiments on monkeys (DeVito et al. 1964), it is known that the discrimination of weights is initially impaired by section of the posterior column but that the capacity to discriminate returns virtually to normal. Weight discrimination is, from clinical evidence, considered to be served primarily by posterior-column systems.

**The somatosensory cortex.** Buried in the central fissure which divides the parietal from the frontal lobe is a narrow strip of highly granular cortex typical of sensory areas in the cortex. On this and the adjacent zone of the postcentral gyrus is concentrated a dense projection of fibers from so-called relay nuclei, which in turn receive fibers of the medial lemniscus and the spinothalamic tract (in primates). This cortical area, called the somato-

sensory cortex, is highly organized topographically, with relatively large portions devoted to the skin areas having the greatest acuity in two-point discrimination and the greatest accuracy in location of a point touched. According to Mountcastle (1961) the receptive field of a single neuron in this region is relatively small but is calculated to be one hundred times that of a second-order neuron. The size of the receptive field is smallest on the fingers and largest on the back, being roughly proportional to the spatial acuity of these regions.

**Detour systems.** In addition to the classical somatosensory pathway, there are three additional pathways, termed *detour systems* (Ruch & Patton 1965) because they, in a sense, bypass the relay nuclei of the classical pathway. One is a projection to the precentral gyrus from a thalamic nucleus which receives input from the cerebellum and, hence, is potentially connected with the various spinocerebellar pathways.

The second is a projection of fibers from the posterior thalamic nuclei to the posterior parietal lobule, a so-called association area, lying behind the termination of the classical pathway. The posterior thalamic nuclei are believed to receive impulses from the classic relay nucleus (some of the most posterior ones receive impulses directly from the medial and spinal lemniscus, but their cortical projection is not known with certainty). At the time these systems were being traced anatomically, behavioral experiments showed that the posterior parietal area could account for discrimination of weights independently of the precentral gyrus (Ruch et al. 1937). Furthermore, the combined destruction of both areas (parietal lobectomy) greatly impaired, but did not abolish, weight discrimination, even in chimpanzees. This and other evidence (Kruger & Porter 1958) indicates that the classical motor area serves a discriminative somatosensory function.

The third set of detour pathways is nonlemniscal and nonspinothalamic in the strict sense but is nonetheless anterolateral in its spinal course. Ascending fibers terminate in or give off collaterals (some are no doubt collaterals of spinothalamic fibers) to the bulbar reticular formation and, at midbrain levels, to the central gray matter, the superior colliculus, and the posterior thalamic nuclei near the medial geniculate body (Mehler et al. 1960). The thalamic nuclei medial to the relay of spinothalamic and lemniscal fibers also receive a stream of the ascending fibers of anterolateral origin, as well as impulses from multisynaptic pathways deep in the reticular formation.

The pathway has been termed the paleospinothalamic tract, to distinguish it from the direct, or neospinothalamic, tract (Bishop 1962). There is considerable reason to believe that the diffuse, multisynaptic, unmyelinated, primitive system of fibers is involved in affect and pain experience.

**Posterolateral tracts.** Throughout this discussion, we have drawn the classical contrast between posterior-column and anterolateral-column pathways. It is now clear that a posterolateral tract of the spinal cord also sends impulses to the somatosensory cortex, with relays in the lateral cervical nucleus. This tract is a fast-fiber system, impulses reaching the cerebral cortex more quickly than those conducted in the posterior columns. Some fibers of this system have restricted receptive fields, while others respond broadly in respect to place and kind of cutaneous stimulation. This system has been studied mainly electrophysiologically, and its significance to sensation relative to the posterior-column and anterolateral-column systems has yet to be assessed.

**Mechanisms of cerebral sensory function.** Four aspects of sensation can be arranged in a presumed order of phylogenetic development: affect, quality, intensity, and localization. *Affect* appears to develop at subcortical levels of the nervous system, probably as low as the midbrain. The *quality* of stimuli can be correctly identified (e.g., touch, warmth) even after extensive cortical lesions, and recognition of quality is probably a thalamic, as well as a cortical, function. The discrimination of fine degrees of *intensity* is a function of the "motor" and "association" areas adjacent to the classic somatosensory area of the postcentral gyrus in the cerebral cortex. Obviously, these two terms do not convey their sensory function.

In the ascending pathways, distortion of a simple stimulus-intensity-frequency-of-discharge arrangement arises from the tendency of second-order neurons and cortical neurons to fire repetitively in response to a single afferent stimulation. Nevertheless, the single thalamic units being fired by limb displacement reflect faithfully, in spikes per second, the degree of joint rotation (Mountcastle et al. 1963). Interestingly, the quantitative relationship between stimulus and response is a power function rather than the logarithmic function postulated by the classical Weber-Fechner law. This finding agrees with and supports the conclusion reached by Stevens (1961) on the basis of psychophysical experiments involving magnitude-scaling procedures and cross-modality ratio matching; such methods are powerful tools applicable widely in the social sciences. [See **PSYCHOPHYSICS**;

**SCALING**; and the biographies of **FECHNER** and **WEBER**, ERNST HEINRICH.]

A broad relation exists between accuracy in localization and the amount of topographical organization in a system, the number of cortical units devoted to an area of skin, and the size of the receptive fields. However, the extent of the receptive fields and of the area of cerebral cortex activated by stimulation of a point on the skin are much too great to permit consideration of any true point-to-point isomorphism between the skin and the somatosensory cortex. Corroborative evidence is provided by the fact that the ramifications of single sensory neurons are so extensive that neurons interdigitate, and that size of the receptive field becomes progressively larger higher up in the nervous system. There are counterparts in the auditory system and in the visual system, where optical errors, light scatter, and small eye movements are also hazards to a conception of a point-to-point relationship between the external world and the visual cortex. It may be speculated that all these errors could have been minimized in the course of evolution. The occurrence of these dispersal processes must mean that they contribute to, rather than detract from, acuity of spatial discrimination. It is probable that in all three sensory systems the nervous system behaves, not in terms of a mosaic of all-or-nothing patches of cortical activation, but in modal points of maximum cortical activation (number of active neurons times frequency of their discharge).

The ability to discriminate modal points of excitability and such devices for sharpening these points as lateral inhibition and descending inhibitory influences on sensory system synapses provide a mechanism by which the fineness of "cortical grain" (i.e., the numbers of cortical neurons) extends discriminative ability beyond what could be achieved if sense organs were arranged in a mosaic, rather than an interdigitating, fashion and were equipped with private pathways to the cerebral cortex. An alternative to this statistical conception of spatial discrimination is a very successful "atomistic" analysis of the visual cortex by Hubel and Wiesel (1965), in which divergence in the system at each synaptic level endows it with increasingly subtle powers of spatial movement and form discrimination.

## SLAVERY

In classical Roman law, slavery was defined as an institution "whereby someone is subject to the dominium of another contrary to nature" (*Digest* 1.5.4.1). *Dominium* can be translated as "power," but the idea of property is also implied. This definition may be accepted as universally applicable without the controversial phrase, "contrary to nature." Distinctions then have to be drawn according to the owner (whether an individual, a corporate institution, the state, or a god), according to the existence or nonexistence of certain "rights" of the slave (such as the claim to eventual manumission, or statutory freedom), and according to the social structure within which slavery functioned. However, the property element remains essential. All forms of labor on behalf of another, whether "free" or "unfree," place the man who labors in the power of another; what separates the slave from the rest, including the serf or peon, is the totality of his powerlessness in principle, and for that the idea of property is juristically the key—hence the term "chattel slave."

For a sociological analysis, however, equal stress must be given to the slave's deracination. The law

The pathway has been termed the paleospinothalamic tract, to distinguish it from the direct, or neospinothalamic, tract (Bishop 1962). There is considerable reason to believe that the diffuse, multisynaptic, unmyelinated, primitive system of fibers is involved in affect and pain experience.

**Posterolateral tracts.** Throughout this discussion, we have drawn the classical contrast between posterior-column and anterolateral-column pathways. It is now clear that a posterolateral tract of the spinal cord also sends impulses to the somatosensory cortex, with relays in the lateral cervical nucleus. This tract is a fast-fiber system, impulses reaching the cerebral cortex more quickly than those conducted in the posterior columns. Some fibers of this system have restricted receptive fields, while others respond broadly in respect to place and kind of cutaneous stimulation. This system has been studied mainly electrophysiologically, and its significance to sensation relative to the posterior-column and anterolateral-column systems has yet to be assessed.

**Mechanisms of cerebral sensory function.** Four aspects of sensation can be arranged in a presumed order of phylogenetic development: affect, quality, intensity, and localization. *Affect* appears to develop at subcortical levels of the nervous system, probably as low as the midbrain. The *quality* of stimuli can be correctly identified (e.g., touch, warmth) even after extensive cortical lesions, and recognition of quality is probably a thalamic, as well as a cortical, function. The discrimination of fine degrees of *intensity* is a function of the "motor" and "association" areas adjacent to the classic somatosensory area of the postcentral gyrus in the cerebral cortex. Obviously, these two terms do not convey their sensory function.

In the ascending pathways, distortion of a simple stimulus-intensity-frequency-of-discharge arrangement arises from the tendency of second-order neurons and cortical neurons to fire repetitively in response to a single afferent stimulation. Nevertheless, the single thalamic units being fired by limb displacement reflect faithfully, in spikes per second, the degree of joint rotation (Mountcastle et al. 1963). Interestingly, the quantitative relationship between stimulus and response is a power function rather than the logarithmic function postulated by the classical Weber-Fechner law. This finding agrees with and supports the conclusion reached by Stevens (1961) on the basis of psychophysical experiments involving magnitude-scaling procedures and cross-modality ratio matching; such methods are powerful tools applicable widely in the social sciences. [See **PSYCHOPHYSICS**;

**SCALING**; and the *biographies* of FECHNER and WEBER, ERNST HEINRICH.]

A broad relation exists between accuracy in localization and the amount of topographical organization in a system, the number of cortical units devoted to an area of skin, and the size of the receptive fields. However, the extent of the receptive fields and of the area of cerebral cortex activated by stimulation of a point on the skin are much too great to permit consideration of any true point-to-point isomorphism between the skin and the somatosensory cortex. Corroborative evidence is provided by the fact that the ramifications of single sensory neurons are so extensive that neurons interdigitate, and that size of the receptive field becomes progressively larger higher up in the nervous system. There are counterparts in the auditory system and in the visual system, where optical errors, light scatter, and small eye movements are also hazards to a conception of a point-to-point relationship between the external world and the visual cortex. It may be speculated that all these errors could have been minimized in the course of evolution. The occurrence of these dispersal processes must mean that they contribute to, rather than detract from, acuity of spatial discrimination. It is probable that in all three sensory systems the nervous system behaves, not in terms of a mosaic of all-or-nothing patches of cortical activation, but in modal points of maximum cortical activation (number of active neurons times frequency of their discharge).

The ability to discriminate modal points of excitability and such devices for sharpening these points as lateral inhibition and descending inhibitory influences on sensory system synapses provide a mechanism by which the fineness of "cortical grain" (i.e., the numbers of cortical neurons) extends discriminative ability beyond what could be achieved if sense organs were arranged in a mosaic, rather than an interdigitating, fashion and were equipped with private pathways to the cerebral cortex. An alternative to this statistical conception of spatial discrimination is a very successful "atomistic" analysis of the visual cortex by Hubel and Wiesel (1965), in which divergence in the system at each synaptic level endows it with increasingly subtle powers of spatial movement and form discrimination.

#### SLAVERY

In classical Roman law, slavery was defined as an institution "whereby someone is subject to the dominium of another contrary to nature" (*Digest* 1.5.4.1). *Dominium* can be translated as "power," but the idea of property is also implied. This definition may be accepted as universally applicable without the controversial phrase, "contrary to nature." Distinctions then have to be drawn according to the owner (whether an individual, a corporate institution, the state, or a god), according to the existence or nonexistence of certain "rights" of the slave (such as the claim to eventual manumission, or statutory freedom), and according to the social structure within which slavery functioned. However, the property element remains essential. All forms of labor on behalf of another, whether "free" or "unfree," place the man who labors in the power of another; what separates the slave from the rest, including the serf or peon, is the totality of his powerlessness in principle, and for that the idea of property is juristically the key—hence the term "chattel slave."

For a sociological analysis, however, equal stress must be given to the slave's deracination. The law

may declare him, in a formal way, powerless and rightless; one reason the law is enforceable is that he lacks any counterweight or support, whether from a religious institution, from a kinship group, from his own state or nation, or even from other depressed groups within the society in which he has become a slave. Legally he is not a person. Yet he is a human being, and therefore a purely juristic analysis in terms of property, though necessary, is not sufficient.

Conceptually, every man has available to him, or is denied, a bundle of rights and obligations as diverse as freedom of movement, the right to the fruits of his labor, the right to marry and establish a family, the obligation (or right) of military service, the right to look after his soul. It is not normally the case that a man possesses either all of them or none; hence the range and variety of personal statuses found in different societies, and, within limits, even inside a single society, are very considerable. One may speak of a spectrum of statuses between the two extremes of absolute rightlessness and of absolute freedom to exercise all rights at all times (Finley 1964). The latter has never existed, nor has the former, although the position of the slave in the American South came very near to it. In between the two extremes, precisely as in a spectrum, there is much shading and overlapping, which the servile vocabulary reflects.

Within the spectrum there are lines of demarcation. Throughout most of human history, labor for others has been performed in large part under conditions of dependence or bondage; that is to say, the relation between the man who works and his master or employer rested neither on ties of kinship nor on a voluntary, revocable contract of employment, but rather on birth into a class of dependents, on debt, or on some other precondition which by custom and law automatically removed from the dependent, usually for a long term or for life, some measure of his freedom of choice and action. "The concept of labor as a salable commodity, apart from the person of the seller, is relatively recent in the history of civilization" (Lasker 1950, p. 114). In all societies in which dependent labor is common, regardless of the variations within that broad class of persons, one main demarcation line is between the dependents and the others.

Slavery is a species of dependent labor and not the genus. Slaves were to be found in many societies in which other kinds of dependent labor—debt bondsmen, clients, helots, serfs, Babylonian *mushkenū*, Chinese *k'o*, Indian Sudras—were common, just as they coexisted with free labor. However, slavery attained its greatest functional significance,

and usually its greatest numerical strength, in societies in which other, less total varieties of bondage had either disappeared or had never existed. The distinction is particularly sharp as between *genuine* slave societies—classical Greece (except Sparta) and Rome, the American South and the Caribbean—on the one hand, and *slave-owning* societies as found in the ancient Near East (including Egypt), India, or China, on the other hand. Only when slaves became the main dependent labor force was the concept of personal freedom first articulated (in classical Greece), and words were then created or adapted to express that idea. It is literally impossible to translate the word "freedom" directly into ancient Babylonian or classical Chinese, and modern European languages cannot render *mushkenum* or *k'o*.

### The slave as outsider

Speculations about the origins of slavery have tended to overlook the specific character of slavery within the broader category of dependent labor. Thus, Nieboer (1900, especially pp. 6–7, 419–430) correctly stresses "division of labor" and scarce resources (including scarce manpower) as necessary conditions, but he misses the point that the needs were usually met in early and traditional societies by such institutions as clientage or helotage rather than by slavery, as they have again been met in many areas in very modern times after the abolition of slavery (Kloosterboer 1960, chapter 14).

The slave is an outsider: that alone permits not only his uprooting but also his reduction from a person to a thing which can be owned. Insiders en masse cannot be so totally transformed; no community could survive that. Thus, free Greeks who wished to dispose of unwanted children were compelled to resort to the fiction that they had "exposed" them (that is, abandoned them in a deserted place); the earliest Roman law code explicitly provided that if a Roman were subject to enslavement as a punishment, he had to be sold abroad (Lévy-Bruhl 1931); Islamic law always laid down, and usually enforced, the rule that no born Muslim could be enslaved.

Any hypothesis about the origins of slavery must therefore explain how and why a given society turned to outsiders either to supplement or to replace its existing labor force. Supplementation on a small scale, such as the retention of female captives, seems both very ancient and very widespread and presents no analytical problems. But the shift to slavery in a fundamental sense, as a substantial labor force employed in production, is a radical step. The explanations cannot be identical in all

instances, because of profound differences in the social structures and economic systems. However, there were always present not only a sufficient material and technical level and a concentration of power which made possible safe procurement of outsiders in sufficient numbers but also the failure, unacceptability, or unavailability of other kinds of labor.

The trauma of enslavement, often entailing great physical suffering as well as severe psychological damage, set up a chain reaction in the behavior of both the slaves and their masters, in which the potential or actual employment of naked force was a permanent and inescapable factor (Elkins 1959). These behavior patterns and their underlying psychology were reinforced by the slave's lack of essential human ties of kin and community. Free sexual access to slaves marks them off from all other persons as much as their juridical classification as property. On the other hand, not all societies went as far as the American South in the absolute denial to the slave of a *de facto* family of his own. There slavery was complete, so to speak, and the slave's deprivation was extended to the next generation; he lost all control not only over his productive activity but also over his reproduction. In consequence, being born into slavery meant being born an outsider, too.

**Prejudice.** Prejudices of color, race, nationality, and religion were deeply involved in slavery, not only as ideological justification but also as influences on its institutional development. "Slavery was not born of racism," writes Williams (1944, p. 7), "rather, racism was the consequence of slavery." However, the question must be asked whether the very idea of enslavement could have been thought of without the extreme distinction between groups, and therefore prejudice, in which "race" in a very loose sense was the criterion. To be sure, Greeks enslaved Greeks from other city-states, for example, and religious conversion, whether to Christianity or to Islam, did not normally release a slave. Nor did community solidarity always prevent penal bondage from sliding into genuine slavery (Pulleyblank 1958, p. 204). These are minor aberrations, however. If one could compile statistics of the number of slaves throughout history according to their origins, the proportion of racial, national, and religious outsiders would be overwhelming. Prejudice was certainly an important factor in the Southern American colonies when they decreed, in the 1660s, that henceforth all Negroes, but no whites, who were imported should be slaves and not indentured servants.

Prejudice had its limits, however. For example,

it never interfered with sexual relations. It allowed Portuguese officials and missionaries to condone Negro slavery in Brazil while they struggled energetically to emancipate the Amerindians (Boxer 1963, chapter 3; Davis 1966, chapter 8). Slaves drawn from culturally advanced peoples, such as the Hellenized Syrians in Rome, were regularly employed in such occupations as medicine and education. The most remarkable groups of elite slaves—the Mamelukes and Janissaries—illustrate all aspects of the slave outsider. In each generation the Mamelukes were purchased as children outside Islam, were given a rigorous and lengthy religious and military training, and were freed when ready for military service. A closed corps was thus created; their only ties were to themselves and their patron (ex-owner), and their elite position was not transmissible to their own children (Ayalon 1960).

### Slave supply

The procurement of a continuous and numerous supply of slaves depended above all on warfare. In early and simple societies, that usually meant raids by the slave-owning society on its source of supply. Even under more advanced conditions, when societies of more or less equal power and culture adjoined each other, regular warfare and raiding may also have been stimulated, at least in part, by the desire for slaves. However, greater stability of supply and greater numbers were ensured in the New World and even to a considerable extent in ancient and medieval times by a more indirect link with war. Neither Portugal nor England made war regularly in Africa in order to meet the demand in the Americas for slaves. The initial act of capture was left to the Africans themselves or to so-called pirates, as it had been left in antiquity to Scythians, Phrygians, and others. In short, the active cooperation of "native" chieftains and tribesmen was critical, and equally so was the role of professional slave traders as the middlemen.

Slave traders often appear as ambiguous figures. The Southern judge who wrote that "the calling of a slavetrader was always hateful, odious, even among slaveholders themselves" (Bancroft [1931] 1959, p. 366) was expressing one common judgment, but not the only one, for in England at the same time "his business was a recognized road to gentility" (Davis 1966, p. 154). In all countries his financial and governmental backers and his customers were thoroughly "respectable" figures in the community, and the high value of his services was always acknowledged. The suggestion that for a century or more the Roman Senate made no seri-

ous effort to suppress piracy in the eastern Mediterranean is probably sound, just as there can be little doubt about influential, though not unchallenged, support for the extensive illicit trade in slaves which followed British abolition after the Napoleonic Wars.

After warfare, breeding was the major source of supply. This is a subject on which much research remains to be done, the results of which will probably confirm the view that no simple generalization is possible. Certainly the often cited "law" that a slave population never reproduces itself is fictitious. In the United States the slaves did better than that, providing a very considerable increase. The question is intimately bound up with many social and economic factors and not with supposedly necessary demographic consequences (biological or otherwise) of the slave status. At one extreme there were conditions such as prevailed in the silver-mining district of Athens, where the slaves were almost all males and therefore could not reproduce themselves. At the other extreme there was the systematic, profitable breeding in the poorer regions of the American South (Conrad & Meyer 1958). In between these extremes, there was a great range of possibilities, conditioned by, among other things, the prevailing rules regarding the inheritance of slave status. These rules appear bewildering in their variety, but much the commonest was that the child took the mother's status.

### The uses of slaves

The actual numbers of slaves in any society are rarely known. The American South provides the decisive exception, and there the figures show an upper limit far below the often repeated exaggerations, such as the 400,000 claimed for ancient Athens. In 1860 slightly fewer than one-third of the population of the American slave states were slaves. Furthermore, "nearly three-fourths of all free Southerners had no connection with slavery through either family ties or direct ownership. The 'typical' Southerner was not only a small farmer but also a nonslaveholder" (Stampp 1956, p. 30). What counts in evaluating the place of slavery in any society is, therefore, not absolute totals or proportions, but rather *location* and *function*. If the economic and political elite depended primarily on slave labor for basic production, then one may speak of a slave society. It does not matter, in such situations, whether as many as three-fourths were not slaveholders, or whether slavery was fairly widespread outside the elite in domestic or other nonproductive roles.

Wherever there are slaves, they will be found in

domestic (and therefore also sexual) roles. Such roles have their own spectrum, ranging from the "drawers of water" and meanest prostitutes to domestics who were occupationally employed by their craftsmen-owners and to eunuchal grand viziers and harem favorites. If, however, this is the social location of most of the slaves, then it must follow that other kinds of dependent (or, on occasion, free) labor together with independent peasants and craftsmen constitute the productive labor force. That was the case in the ancient Near East, China, India, and medieval Europe and Byzantium as well as the Islamic world of the same period, and it is still the case in Saudi Arabia.

**The economics of slavery.** Slavery, then, is transformed as an institution when slaves play an essential role in the economy. Historically that has meant, in the first instance, their role in agriculture. Slavery has been accommodated to the large estate under radically different conditions: the Roman *latifundia* did not practice the monoculture of the modern plantation, and they existed within an essentially precapitalist economy. However, both types of estate produced for the market, and they both existed alongside widespread free small holding. That both slaves and free men did identical work was irrelevant; what mattered was the condition of the work, or rather, on whose behalf and under what (and whose) controls it was carried on. In slave societies hired labor was rare and slave labor the rule whenever an enterprise was too big for a family to conduct unaided. That rule extended from agriculture to manufacture and mining, and sometimes even to commerce and finance. In this article it is impossible to examine in detail these other uses of slaves, because of all the complexities involved and the extent to which they vary from society to society. A number of variables are involved: the poverty of the soil, as in Athens and other Greek cities; the special position of a particular region within an international network of economic relations, as in the American South; or the special role of the state as a large consumer of manufactures, as in the later Roman and Byzantine empires.

As an economic institution, slavery was "profitable"; this can be asserted with confidence, despite frequent attempts to deny it. In the strict sense of the term, the question of profitability does not enter into an evaluation of domestic slaves, court eunuchs and concubines, or Mamelukes. Nor is there any value in hypothetical arguments about whether or not Roman senators could have managed their *latifundia* even more profitably with some other kind of labor force. They made very large fortunes

for centuries on end, and there is no other way to calculate the economics of slavery in a precapitalist society. As for the American South, it can no longer be seriously questioned that slave plantations were profitable "in a strict accounting sense" (Genovese 1965, p. 280), whatever the effects of slavery on further economic growth within a competitive world economy. In the accounting, it is important to give proper weight to the profitability of slave breeding in the agriculturally poorer regions. In addition, there were the profits of the slave trade, which might or might not accrue to members of the slaveholding society itself.

### Slaves and masters

The difficulties in properly understanding the personality and the psychology of the slave are obvious. Neither the remarks by contemporary writers (whether slaveholders or outside reporters) nor the relatively few documents emanating from slaves themselves can be taken at face value. Yet a special slave psychology must have developed (speaking in group terms, of course). In order to survive as human beings, slaves had to adapt to their new state of deracination by developing new psychological features and new focuses of attachment, including their overseers and masters. Slave elites, whether individual overseers or whole groups of slaves and freedmen (ex-slaves), such as the imperial *familia* in Rome or the Mamelukes in Egypt, serve to exemplify how far adaptation and acceptance could be pushed under certain conditions. The slave-type—the clever schemer of Greek and Roman comedy or the childlike, indolent, amoral Sambo familiar to American literature and popular humor—is no doubt a stereotype and a caricature, but, as Elkins (1959, chapter 3) has argued, it cannot be a pure invention out of nothing.

**Slave rebellions.** The slave was a "troublesome property" (Stampp 1956, chapter 3). In its most extreme form, "being troublesome" meant revolt, but large-scale revolt is extremely difficult to organize and has, in fact, been a relatively rare phenomenon in the history of slavery. Throughout classical antiquity there were only three revolts of any mark, each involving 100,000 or more slaves, and all concentrated within the short time span of 135–70 B.C. Common to all three were the presence of certain necessary conditions, including a severe breakdown of the social order and the concentration of large numbers of slaves with common nationality, language, and culture, among them men with unusual potentialities of leadership (Vogt 1957). It is important to contrast the ancient chattel slaves with the helots (in Sparta and elsewhere)

in this respect: the latter were permanently mutilous in an organized way, presumably because they belonged to a class of dependent labor which retained the normal human ties of solidarity with kin and community. The Caribbean throughout the eighteenth and early nineteenth centuries was also an area of persistent revolt. In the United States, under conditions which differed above all by being noncolonial, not a single serious revolt ever occurred; for example, the "Turner cataclysm" of 1831 was a purely local affair lasting a few months from its inception (with only three days of actual fighting) and involving only some hundreds of men (Aptheker 1943, chapter 12).

"Being troublesome," in sum, usually meant something much less than outright rebellion, such as flight, sabotage, theft, and inefficiency. None of these is expressible in quantitative terms or easy to evaluate. There is American evidence to support the famous judgment of the economist Cairnes (1862) that slave labor was on the lowest level of skill because slaves were both uneducated and uncooperative (Genovese 1965, chapter 2). On the other hand, the possibilities of "loyalty," which is equally immeasurable, cannot be ignored. In contrast to American slaves, the slaves of ancient Greece and Rome were regularly and successfully employed in the most highly skilled occupations. Relative mildness or harshness of treatment cannot be a sufficient explanation of such variations, which must lie deep in the social structure and in psychology. Likewise, variations in the practice of manumission, in the place of freedmen in the society, and in the accompanying psychology require complex explanations.

**Attitudes of the masters.** In the ancient world the institution of slavery was never challenged, despite the notion that it was "contrary to nature." No serious argument was ever put forward for the abolition of slavery in ancient Greece and Rome (as distinct from relative liberality in freeing individual slaves), on moral or any other grounds; this was also the case in India, China, and the Islamic world. Nor did Christianity change the fundamental attitude after it became the official and more or less universal religion of both the western and eastern halves of the Roman Empire. Slavery declined sharply at the end of antiquity, but for reasons having nothing to do with moral ideas. Furthermore, it was in the Christian states in southern and southwestern Europe that slavery was considerably revived in the late Middle Ages (Verlinden 1955), and it was among the Christian conquerors of the New World that it received its newest and most vigorous re-creation. Paradoxically, it was

then that the most powerful and persistent claims were put forward for the "naturalness" of slavery, with ample quotation from the Bible, and that moral arguments for the *abolition* of slavery were fully mustered for the first time.

The whole subject of the psychological effects of slavery calls urgently for further investigation—from the side of the masters (including the free poor who themselves owned no slaves) as well as from the side of the slaves. The need to be brutal, ideologically as well as physically, must have had repercussions on the master's psyche. The easy sexual access to slave women influenced all attitudes toward sex and women: witness the quasi-chivalric ideology of Southern womanhood. Furthermore, the identification of certain forms of physical labor with slavery, including the essential labor in agriculture, had its effects on the free man's choice of employment and on his spirit of enterprise generally. More often than not, the majority of free farmers and craftsmen, out of necessity, performed labor similar to that of the slave. Even then, however, there were subtle effects on the directions into which creative talents and energies were channeled, and there were certain employments into which it was extremely difficult to move the free poor when they were needed. Policy makers in underdeveloped countries are still coming up against just such resistance (McLoughlin 1962), although it usually follows the abolition of forms of dependent labor other than slavery.

### Slavery and Marxist theory

Marxist theory, by its very nature, has assigned a unique historical position to slavery. History is viewed as a progress through a number of stages, each genetically determined within its predecessor and each founded on a particular mode of production (social relations of production), of which one is slavery. In the past half century, in particular, the way in which historical analysis was enmeshed in, not to say dominated by, current political discussions produced among orthodox Marxists a rigid, universal, unilinear scheme of development in five stages: primitive communism, slavery, feudalism, capitalism, and socialism. Even the ancient Near East and ancient China, it was held, were slave societies, and there were persistent but wholly unsuccessful efforts to discover general laws or general features common to all slave societies.

However, scattered through Marx's writings down to the early 1860s there are also brief, not fully developed references to an "Asiatic mode of production." His only attempt to examine this systematically was in one section of a bulky manuscript written in 1857–1858 but not published

until 1939–1941 and not widely known before the 1950s. In this sophisticated account, the Asiatic mode of production is characterized as one in which there was no private property in the land and in which a despotic government ruled over the village communities, whose members were in a condition of "general slavery" and who were therefore not slaves in the chattel sense at all. Publication of this work has sparked a very intense new discussion, following a hiatus of nearly a generation (Pećirka 1964). The discussion is still in an early and fluid state, but the general trend seems clear. It is argued that the stages of evolution in European history from which the traditional scheme was constructed do not constitute a model for world history at all but were, on the contrary, a unique development. As a corollary, the "Asiatic" mode of production has been found on other continents as well, for example in Bronze Age Greece and among the Incas. The place of slavery in Marxist theory thus seems to be undergoing a redefinition to fit a multilinear pattern of development.

### BIBLIOGRAPHY

No serious full-scale history of slavery exists in one book. The books and articles listed here, with the bibliographies they include, cover the field quite thoroughly. For classical antiquity, Wallon 1847 is still valuable for its rich documentation. The one modern book on antiquity, Westermann 1955, is recognized to be unsatisfactory; a better, though not systematic, introduction will be found in the 11 articles collected in Finley 1960. For the fullest survey of modern views since the work of David Hume, with a Marxist critique, see Lentsman 1963, Part 1. On the historiography of American slavery, see Elkins 1959, Chapter 1, and the massive literature cited in the notes in Davis 1966; for the new discussion initiated by Elkins, see Sio 1965. On the unresolved controversy about Latin American, and especially Brazilian, slavery, see Elkins 1959 for the view that there has been considerable amelioration, as contrasted with North American slavery, and Davis 1966, Chapter 8, for the opposing view. Summaries of current Marxist discussions of the "Asiatic mode of production," with particular reference to slavery, will be found in Pećirka 1964 and Chesneau 1965, both of whom write as Marxists. An important stimulant of this discussion has been the publication of Marx 1857–1858.

## SLEEP

Historically, there has been concern with two major questions about sleep: What specific mechanisms start, maintain, and terminate sleep? What functions does sleep serve? In addition, there has been considerable interest in the relationship of sleep to learning and performance, as well as in abnormalities of sleep behavior.

**Causes and processes.** The oldest theories about the causes of sleep postulated either congestion or anemia of the brain. More recent hypotheses have attributed sleep to arterial anoxemia, endocrine periodicities, functional neural blocks, or the accumulation of fatigue products. Piéron's idea of a "hypnotoxin" that accumulates during waking and is metabolized away during sleep (1913, p. 520) is one of the best-known explanations. A large number of biochemical studies on blood and other body fluids (reviewed by Kleitman 1939) have failed to turn up evidence in support of any of these hypotheses. The anoxia theory was controverted by the finding that the oxygen content of blood was normal during sleep and that cerebral blood flow was actually increased. The toxin theory was seriously challenged by the finding that Siamese twins with a common blood supply failed to show synchronized sleep-wake rhythms. However, knowledge of the biochemical processes taking place within the sleeping brain is not sufficient to accept or reject the causal influence of chemical factors. At present, these and similar theories of the causes of sleep are not in fashion.

**Electrophysiological mechanisms.** Since the 1930s, the development of electrophysiological techniques has facilitated new approaches to the processes of sleep. Interest has focused on the elucidation of the specific brain mechanisms responsible for the onset and termination of sleep. It is now well established that wakefulness results from activity in the ascending reticular system of the brain stem. However, the central mechanisms for the onset and maintenance of sleep are not so well understood.

The reticular activating system, which originates in the reticular formation of the lower brain stem and extends upward to the hypothalamus, subthalamus, thalamus, and cortex, receives collaterals from all sensory pathways as well as from the cortex. Stimulation of the reticular system by any of these sources or by such biological products as norepinephrine is accompanied by behavioral activation and alertness. Arousal is usually sustained after removal of the stimulus. Lack of stimuli or lack of stimulus variation has soporific effects. [See NERVOUS SYSTEM, article on STRUCTURE AND FUNCTION OF THE BRAIN.]

Since the publication of Kleitman's evolutionary theory of sleep, most physiologists have accepted the "stimulus deficiency" explanation of sleep (1939). The onset and maintenance of sleep are said to be a result of reduced afferent stimulation that deprives the cortex of its sensory raw material. The resulting "deactivation" of the reticular system is, indeed, an important sleep-inducing

mechanism. Everyday experience indicates that in man and animals the preparations for sleep include the suppression of external stimuli. Destruction of the reticular system produces sleep as well as electroencephalographic (EEG) patterns indicative of sleep.

More recent evidence, however, does not fully support this view of sleep as a passive phenomenon. In fact, it strongly suggests the existence of active, sleep-producing mechanisms in the central nervous system. Low-frequency stimulation of several brain locations from the lower brain stem to the thalamus produces sleep, in contrast to the arousing effects caused by high-frequency electrical stimulation of the reticular system. Barbiturate infusion at most brain levels induces sleep, but at some locations induces waking. It is true that changes in the internal milieu, such as reduced blood pressure and low body temperature, contribute to sleep and that familiar or unchanging external stimuli favor sleep, but these conditions are not sufficient to maintain sleep. There is behavioral and physiological evidence to support the hypothesis that there are two mechanisms in the brain for the control of sleep and waking: an activating and a deactivating system. The many degrees of wakefulness and sleep probably result from complex interactions between these two systems, involving the interplay of numerous structures in the nervous system.

**The sleep-wake rhythms.** Most living things show alternating activity and quiescence in response to the alternation of day and night. Higher animals show polyphasic or monophasic and diurnal or nocturnal patterns, depending on their adaptive requirements. These "circadian" (*circa, dies*) rhythms seem to be determined primarily by internal mechanisms but usually can be "reset" by environmental pacemakers, such as night and day. Some biological cycles are remarkably persistent, whereas others are easily modified by environmental changes.

The cerebral cortex may have a unique role in the maintenance of sustained sleep and waking. All animals capable of adjusting their sleep-wake cycles to the monophasic diurnal rhythm of man have a well-developed cortex. Removal of the cortex in such animals causes reversion to polyphasic sleep cycles.

The sleep-wake cycles of rats, rabbits, puppies, and human infants are polyphasic. Monkeys and higher mammals, as well as many birds, have monophasic diurnal cycles. Attempts to modify the diurnal rhythm in man include two types of manipulation: alteration of the phase and alteration of the period of the sleep-wake cycle. The phases of sleep

and waking can be easily modified (as in shifts to night work), but attempts to alter the 24-hour period to days of 12, 48, 21, or 28 hours have had only limited success. Some subjects adjusted to 21-hour or 28-hour days, but none adjusted to 12-hour or 48-hour cycles. A practical requirement for readjusting the phases of sleep and waking occurs when travelers move across lines of longitude. World travelers (especially on long-distance flights) experience phase-shift asynchrony in the day-night cycle, which may cause emotional distress and impaired performance. It seems that about two weeks are needed for a complete diurnal readjustment of physiological rhythms.

A number of physiological rhythms vary with man's sleep-wake cycle. Among these are heart rate, skin resistance, and muscle tonus. One measure of considerable interest is the diurnal temperature cycle. Temperature is normally maximal by day and at its lowest in the early hours of the morning. Several studies have shown that performance efficiency, especially speed, is highly correlated with the temperature cycle. The diurnal variation of both temperature and efficiency are probably related to the establishment of a circadian rhythm of excitement in the reticular system and hypothalamus. Prolonged disregard of normal biological rhythms may lead to genuine, although poorly understood, "rhythm diseases" anchored in disturbed autonomic functioning. [See TIME, article on PSYCHOLOGICAL ASPECTS.]

Sleep seems to be a parasympathetic phenomenon. During normal sleep, general metabolism slows down. Heat production and body temperature decrease, heart rate and respiration decrease, blood pressure is lowered, and  $\text{CO}_2$  tension increases. Kleitman (1939) has pointed out, however, that most of these changes could be simply a consequence of the prone position or of muscle relaxation, independent of sleep.

*Physiological cycling during sleep.* During the waking state, the resting normal human with eyes closed usually displays a continuous EEG pattern of 8 to 12 cycles per second, which is known as the "alpha" rhythm. As he drifts into sleep, the alpha rhythm disappears and is replaced by a low-voltage pattern with irregular frequency. During this phase, thresholds for responding to environmental stimuli are about the same as those in the waking state. As sleep continues, the background EEG voltage becomes higher and the frequency of the rhythms decreases, until the deepest stages of sleep are reached. In the deepest stages, the EEG record is composed of low-frequency, high-voltage "delta" rhythms, and it is very difficult to waken the subject. Approximately 90 minutes after the onset of

sleep, the high-voltage patterns disappear and are replaced by a low-voltage irregular phase similar to that seen at the beginning of sleep. This cycle of alternating slow high-voltage and faster low-voltage rhythms recurs with a period of about 90 minutes. The emergent low-voltage pattern has commonly been believed to be a "light" phase of sleep, but recent experiments show that thresholds for awakening are often very high during this stage. [See NERVOUS SYSTEM, article on ELECTROENCEPHALOGRAPHY.]

Other physiological measures also suggest a 90-minute period as a unit of sleep time. Changes in such physiological and behavioral variables as skin conductivity, heart rate, breathing rhythms, eye movements, and reports of dreaming occur cyclically and in phase with the EEG cycle. Increased heart rate, rapid eye movements, and reports of dreaming occur during the low-voltage phase.

The EEG of cats, rats, and monkeys also show alternating slow high-voltage and fast low-voltage patterns during sleep. Jouvet (1961) has shown that the high-voltage phase in cats is controlled by cortical mechanisms, and the low-voltage phase by pontine and limbic structures. EEG recordings obtained simultaneously from deep brain structures, cortex, and scalp suggest that in the cat the low-voltage phase of sleep involves hindbrain "sleep" and forebrain "wakefulness." The stage is accompanied by inhibition of motor activity, reduced heart rate and blood pressure, very high thresholds for awakening, and rapid eye movements. There is evidence, then, that during the low-voltage "dreaming" stage of sleep at least part of the brain is highly activated. But the very high response thresholds to auditory and other stimuli are difficult to interpret. Some studies show that auditory stimuli that warn of immediate and severe consequences are responded to in this stage as readily as in the other low-voltage phases of sleep. Thus, during dreaming the subject appears to be controlled by interoceptive stimuli and seems to block out external signals unless they have poignant significance.

The cyclical sequence of EEG patterns of sleep in man appears to be quite stable, both from night to night and from subject to subject. Disturbance of these patterns by "deprivation" of either high-voltage or low-voltage EEG phases causes increasing amounts of the disturbed phase to appear on succeeding nights, as if compensation were necessary. Continued deprivation of the low-voltage "dreaming" phase causes irritability and unease.

*Sleep loss and biological functions.* Is sleep a vital function? One way to test this is to deprive an organism of sleep. Several animal studies have shown that prolonged loss of sleep results in death.

A number of human subjects have stayed awake 200 hours or more without sustaining serious physical damage, but after 120 hours without sleep, most subjects developed reversible delirious or psychotic states characterized by visual hallucinations, delusions of persecution, disorientation, and confusion. The psychosis of sleep deprivation, which disappears after normal sleep, is a model mental illness that has considerable significance for experimental psychiatry.

If sleep plays a vital role in biological survival and psychological health, precisely what is this role? It has been suggested that sleep has three main functions: (a) restoring metabolic balance, (b) permitting recovery from muscular fatigue, (c) aiding neural reorganization. With few exceptions, studies of sleep loss have not given positive support to any of these hypotheses. Most systems of the body hold up remarkably well with loss of sleep.

*Metabolic effects.* One recent study of sleep loss, however (Luby et al. 1960), has shown striking metabolic effects. After the fourth day of sleep deprivation there was evidence of a drastic breakdown in the manufacture of adenosine triphosphate (ATP), the substance that provides energy for a host of biological processes. Thus, the high-energy transfer systems of cell metabolism showed gross impairment. This metabolic dysfunction was accompanied by rapid deterioration in personality and performance. These findings are congruent with the hypothesis that the catabolic processes that predominate during the waking state are compensated for during sleep; that sleep permits the restoration of energy and anabolic compensation.

*Effect on performance.* During sleep loss the subject shows deficits in performance that are similar to those observed with fatigue. The deficit takes the form of lapses (brief periods of poor performance), which in the sleep-deprived subject are accompanied by extreme drowsiness, intrusive thoughts, visual illusions, and dreams. They are preceded and accompanied by a slowing of heart rate, breathing, and EEG rhythms. Lapses increase in frequency, duration, and depth as the period without sleep progresses until the subject reaches a kind of hypnagogic state in which the background EEG pattern resembles a light phase of sleep. The frequency of lapses during sleep loss is increased by monotony or by prolonged performance and is decreased by incentive. The main effects of these brief periods of extreme drowsiness are slowed reactions. The subject is usually able to sustain accuracy if given sufficient time. Tasks extremely sensitive to sleep loss are those that are prolonged,

repetitive, and work-paced, impose a high speed-load, and provide low incentive (Williams et al. 1959).

As sleep loss increases, other mental functions are affected. For example, the ability to store and retrieve new information is greatly impaired. Finally, when most data-processing functions are seriously debased, the subject becomes psychotic. Some goal-directed, sequential, and rational behavior remains, however. Even after seven days of sleep deprivation, subjects can pull themselves together for short-term problem-solving and can carry out well-learned, perhaps automatic, sensory-motor tasks.

Performance decrement and personality aberrations during sleep loss follow the diurnal temperature cycle. Effectiveness reaches a low point late at night (when body temperature is at its lowest) and improves during the next day, even though the amount of sleep loss has increased.

*Interaction with other stress.* There are at present very few reports on the combined effects of sleep loss and other types of stress. The available studies indicate that the effects are not readily predictable from a knowledge of the independent effects of each form of stress. For example, Wilkinson (1963) has shown that high-intensity background noise normally causes impaired performance on vigilance and choice reaction-time tasks. But the degrading effect of noise is reduced after a night of sleep loss. Apparently, noise and sleep deprivation produce different types of fatigue. With sleep loss, the level of stimulation required for arousal is too low; with noise, it may be too high. Similar complexities appear in studies that combine raised body temperature with sleep loss. Recent unpublished studies suggest that for the sleep-deprived subject a moderate increase in body temperature (say, one degree) improves performance, but that higher temperatures act synergistically with sleep deprivation to cause severe decrement in both speed and accuracy.

*Fatigue at skilled tasks.* The word "fatigue" usually refers to the changes in muscle metabolism that occur with prolonged exertion. A vast amount of research has been done on this topic, but it will not be discussed in this article. There are, however, many prolonged tasks requiring very little muscular effort, during which performance declines and the subjects report fatigue. The general nature of impairment at such tasks was first described by Bills (1931). He observed that performance did not decline as a simple function of time at the task, but instead became increasingly uneven. Adequate performance was interrupted from time to

time by "blocks," or brief periods of no response, which increased in frequency and duration with continued mental work. Bills attributed mental blocks to "a recurrent low condition of mental functioning." [See *FATIGUE*.]

In recent years the prototype task for the study of prolonged performance has been the so-called vigilance test. During such a task, an observer watches or listens for long periods for critical signals that occur from time to time in a background of neutral signals. Radar and sonar operations are practical examples of such tasks. During the course of an hour's performance, the proportion of signals missed is low at first, but after 15 to 30 minutes increases rapidly. These errors of omission are increased by monotony, by distraction, and by states of physiological depression such as those caused by sleepiness, low oxygen pressure, high nitrogen pressure, and tranquilizing drugs. Performance improves under incentive, and the drug amphetamine largely prevents the decline in efficiency. Thus the effects of prolonged performance are similar to those seen with sleep loss. Presumably, the decrement is due to recurrent periods of lowered cerebral vigilance. It is not certain whether these phases represent increased distractibility or simply drowsiness, or both. Very few studies have used continuous physiological monitoring during prolonged performance, but the available reports suggest that the physiological changes accompanying performance decrement are similar to those that accompany the lapses of sleep deprivation. [See *ATTENTION*.]

**Learning and performance during sleep.** There is no convincing evidence that learning can occur during sleep. The sleeping state seems to be incompatible with many forms of cognitive behavior. Simon and Emmons (1955) in a well-controlled series of experiments showed by continuous EEG monitoring that humans failed to learn items of information during actual sleep. Their results challenge all earlier studies purporting to show that learning can be induced during sleep, and they cast great doubt on the claims of numerous commercial enterprises that advertise sleep-learning methods.

However, negative results in one well-controlled study do not prove that all forms of learning are impossible in the sleeping state. Failure to induce learning may have been due to procedural problems. Simon and Emmons used only one night of training. There was no effort to "shape" complex responses from simpler behavior or to elucidate the precise stimulus attributes, incentive conditions, and response requirements that might be compatible with the sleeping state. The cyclic rise and fall

of EEG activation patterns during sleep suggests that there may be some phases of sleep in which learning is possible.

The ancient observation that some discrimination is possible in sleep has been confirmed by recent experiments. Cats are capable of remarkably fine discrimination of auditory signals while asleep. Humans can discriminate between complex auditory patterns, make appropriate motor and physiological responses to conditioned stimuli, respond differentially to warning signals and neutral signals, and perform well-learned motor sequences without awakening.

**Sleep disorders and sleep therapy.** The many abnormalities of sleep are well known. They include excessive sleep, inability to sleep, restless sleep, nightmares, bed-wetting, sleep paralysis, and other problems. Neurologists classify sleep disorders under three headings: hypersomnia, insomnia, and nocturnal behavioral symptoms. All three can occur with brain disease or with psychological etiology.

**Hypersomnia.** Narcolepsy is a condition of hypersomnia characterized by sudden sleep seizures at inappropriate times. The syndrome also includes sleep paralysis and cataplexy. The irresistible desire to sleep may occur several times daily, especially after heavy meals, during periods of low body temperature, or during monotonous activity. The duration of sleep varies from a few seconds to several hours. Hypnagogic hallucinations often precede and accompany the attacks of sleep.

Narcolepsy occurs in both idiopathic and symptomatic forms and may follow a chronic course for as long as forty years. Recently, a genetic factor has been identified in a group of patients with idiopathic narcolepsy (Yoss & Daly 1960). The idiopathic form usually appears during adolescence and is more common among males. The condition can be treated symptomatically with analeptic drugs.

**Insomnia.** Insomnia, or hypsomnia, is also associated with a variety of pathological states including brain tumor, metabolic disease, circulatory disorders, and aging. It is a common precursor of acute schizophrenic reactions and, of course, accompanies general emotional upset, depression, or anxiety. The hypsomnia may occur at the onset, during, or at the termination of sleep. Clinical observers have reported that difficulty in falling asleep is a common symptom in anxiety neuroses, whereas frequent and early awakening from sleep is a classic feature of depressive illnesses. Insomnia is usually a difficult treatment problem, although drugs, psychotherapy, and relaxation-training are often effective.

**Nocturnal behavioral symptoms.** Behavioral symptoms during sleep—including night terrors, sleep-walking, enuresis, grinding of teeth, delirium, and nightmares—can occur with specific disorders of the nervous system or as transient symptoms in normal individuals. All of these abnormalities may have some connection with aberrations of normal dreaming. Nearly all involve dreamlike activity and tend to occur during low-voltage EEG phases.

**Sleep therapy.** Sleep can be learned as a response in order to reduce anxiety. Since the excessive sleeper may use sleep to "narcotize" anxiety, it may be supposed that sleep would be useful as an adjunct to psychotherapy. Sleep therapy was first used in Switzerland, but it has achieved greatest popularity in the Soviet Union. As a consequence of Pavlov's theories, prolonged sleep is used to "protect" the brain during mental illness. It is said to be most effective in cases of catatonic excitement, depression, and acute anxiety, but no controlled experimental studies were located. [See MENTAL DISORDERS, TREATMENT OF, article on SOMATIC TREATMENT.]

**Conclusion.** Since the first comprehensive summary of sleep and wakefulness by Kleitman (1939) there has been a considerable increase in scientific interest in the problem. At that time there were about thirteen hundred references in the literature. There are now more than four thousand. Research activity is much greater, however, in neurophysiology than in psychology or other disciplines. Psychologists for the most part seem to have taken the transition from waking to sleep as a natural boundary for the study of behavior. Sleep, however, is not behaviorally empty. Even in deepest sleep subjects retain responsiveness to external stimuli. This finding that a considerable amount of behavior can be induced during sleep raises some interesting problems for both psychologists and neurophysiologists. If sleep is not, behaviorally, a silent state, what limits does sleep impose on the organization of behavior? If the pattern and meaning of auditory signals can be recognized by the sleeping subject, how are we to define sleep? How is the central nervous system organized during the sleeping state?

A few answers have been suggested to the fundamental questions raised by the identification of similar cyclic patterns of sleep in man and animals. The discovery of the physiological correlates of dreaming permitted the development of entirely new concepts relating animal to human subjective states. But as research increases, questions multiply. Do animals dream? Is the dreaming phase in man under the control of the limbic system? What organizing concept in neurophysiology will ac-

count for the simultaneous high activation levels and high response threshold seen in the emergent low-voltage stage of sleep?

The age-old questions of the causes of sleep, the biological functions of sleep, the neural and humoral mechanisms of sleep, the effects of distributed sleep, and the modifiability of the sleep-wake cycle are only partially answered. Clearly, research on the psychological, physiological, and social properties of sleep has important implications for all of the life sciences. There are practical reasons, too, for the brisk developments in this field. The requirements of space flight, of modern industry, and of military operations put the subjects of sleep and waking, and of biological rhythms in general, into challenging perspective.

### SLUTSKY, EUGEN

Eugen Slutsky, or Evgenii Evgenievich Slutskii (1880-1948), Russian economist, statistician, and mathematician, was born in Yaroslavl province, the son of a schoolteacher. He entered the University of Kiev as a student of mathematics in 1899 but was expelled three years later for revolutionary activities. From 1903 to 1905 he studied engineering at the Institute of Technology in Munich. After the revolution of 1905 he returned to Russia, obtaining a degree in law from the University of Kiev in 1911. For a while he taught jurisprudence in a technical college, but he became interested in political economy and in 1918 he received a degree in that subject and became a professor at the Kiev Institute of Commerce. In 1926 he left Kiev for Moscow to join the Kon'iunkturnyi Institut (i.e., the Institute for the Study of Business Cycles). From 1931 to 1934 he was on the staff of the Central Institute of Meteorology. Moscow State University conferred an honorary degree in mathematics on him in 1934. From that time until his death he held an appointment at the Mathematical Institute of the Academy of Sciences of the Soviet Union.

One of Slutsky's first published works was his famous article on the theory of consumer behavior (1915). Slutsky here developed some ideas of F. Y. Edgeworth's and Vilfredo Pareto's on the relationship between the utility function and prices, income, and consumption. His main achievement was to show that, with money income fixed, any change in the price of a commodity can be divided into two parts. The first part is the change in relative prices, with real (not money) income fixed. This is called the substitution effect; the consumer maintains approximately a given indifference level.

The second part is the balance of the price change (a proportional shift in all prices), which can be translated into an equivalent change in money income, with prices constant, causing a variation in real income. This is called the income effect; the consumer shifts from one indifference level to another. The two effects turn out to be independent and additive ("Slutsky's relation").

The distinction drawn between the substitution effect and the income effect is often left ambiguous. There is a choice as to whether to define the holding of real income fixed as (a) holding the consumer's utility fixed, or (b) holding a Lespeyre measure of the purchasing power of his money income fixed. Slutsky clearly uses (a) in his mathematical analysis and (b) in his verbal explanation. The difference is, however, of the second order of smalls and unimportant when considering small changes in price. (For a further discussion of this point, see Mosak 1942.)

Although in R. D. G. Allen's opinion (1950) the present theory of consumer behavior is as much a development of Slutsky's work as of Pareto's, Slutsky's paper attracted no attention until Allen discovered it in the mid-1930s (1936).

In his later years Slutsky did very little work in pure economics but made a considerable contribution to mathematical statistics and the theory of probability. His first paper on this subject, "On the Criterion of Goodness of Fit of the Regression Lines and on the Best Method of Fitting Them to the Data" (1913), was written eight years before the work of R. A. Fisher on the same subject. Slutsky was interested in the problem of formalizing the theory of probability. In the article "Über stochastische Asymptoten und Grenzwerte" (1925) he examined the accurate definition of the concept of asymptotic convergence in probability, and so made an important contribution to the theory of probability (see also 1928; 1938).

Slutsky was one of the originators of the theory of stochastic processes. In his work "The Summation of Random Causes as the Source of Cyclic Processes" (1927) he proved that the "periodical" oscillations in economic, meteorological, and other time series do not necessarily show the presence of any underlying periodic cause; such oscillations are typical of all serially correlated random sequences, including those which result from taking a moving sum in a sequence of mutually independent, purely random quantities. By repeatedly smoothing such sequences, one can obtain a new sequence, which will in any limited period of time be closely approximated (with probability one) by a sine curve. This effect of averaging random

series was studied by Slutsky independently of G. U. Yule.

Slutsky's study of stochastic processes centered on serial, or lag, correlation, that is, correlation between two members of a time series separated by a fixed time interval. In many important applications serial correlation depends only on interval length, not on position along the time series. The concept of serial correlation has broad applications in many branches of science and technology, including radio engineering. Slutsky's theory was generalized by A. Khinchin (1934).

Slutsky wrote several articles on the estimation of parameters of stochastic processes. His complete works on the theory of probability and mathematical statistics have been published (see *Izbrannye trudy*).

In the last years of his life Slutsky studied the problem of computing tables for functions of several variables. This work resulted in the posthumous publication of *Tablitsy dlia vychisleniia nepolnoi  $\Gamma$ -funktsii i funktsii veroiatnosti  $\chi^2$*  (Tables for the Computation of the Incomplete  $\Gamma$ -function and the  $\chi^2$  Probability Distribution; 1950).

A. A. KONÜS

SMALL, ALBION W.

Albion Woodbury Small (1854-1926) did more than any other American sociologist to establish the recognition of sociology as an academic subject, and he shared with Lester F. Ward and Franklin H. Giddings the leading role in defining the scope and status of sociology among the social sciences.

Like many sociologists at the turn of the century, Small was initially trained in theology, but in his case that training had been greatly broadened and secularized before he began to teach sociology. After graduating from Colby College in 1876 and from the Baptist Newton Theological Seminary in 1879, he spent two years studying at Berlin and Leipzig. There he was deeply influenced by such historical economists as Gustav Schmoller and by such welfare economists as Adolf Wagner and Albert Schäffle. He read Karl Marx with sympathy but never became a convert. After returning to America, Small taught history and political science for several years at Colby before obtaining a doctorate in 1889 from the Johns Hopkins University. There he specialized in history and political science but was impressed by welfare economics as taught by Richard T. Ely; sociology was not offered at Hopkins at that time. The influence of the welfare economists and admiration for Ward led Small to find the ultimate justifica-

tion of sociology in its stimulation and guidance of sound social planning and in its development of a reliable body of secular social ethics.

**Establishing sociology as a profession.** In 1889 Small became president of Colby and remained there until 1892, when he was appointed to the first chair of sociology in the United States, at the newly founded University of Chicago. There he built the first, and long the best, department of sociology in the United States, appointing in the early years George E. Vincent, W. I. Thomas, Charles R. Henderson, and, somewhat later, Robert E. Park and Ernest W. Burgess. With Vincent, Small wrote the first sociology textbook, published in 1894. Continuing as chairman of the sociology department until his retirement in 1925, Small also served as dean of the graduate school after 1905. Throughout his academic career, he was respected not only as an administrator but also as a conscientious and informative teacher.

Small founded the *American Journal of Sociology* in 1895 and edited it for the next 30 years. It was long the only substantial sociological journal in the United States and for that time the best in the world. Through this medium Small exerted a dominant influence in extending academic and public interest in sociology as well as in raising the standards for sociological literature. He did much to familiarize young scholars with German sociology, an ever more important service as the number of Americans studying for their doctorates in Germany decreased. Small helped to establish the American Sociological Society in 1905 and served as its president from 1912 to 1913. Until his retirement he was one of the most energetic leaders of the society, assuming the task of editing and publishing the *Annual Proceedings* of its meetings. He was also prominent in international sociological activities and served as president of the Institut International de Sociologie in 1922.

**Contributions to sociology as a discipline.** Although Small may ultimately be remembered for his lifelong campaign to establish sociology as a valid field of academic endeavor rather than for his intellectual contributions, the development of his ideas nevertheless exemplifies a general trend in sociology during his lifetime. This trend, as Small assessed it, was a transition from primary attention on relatively static social structures to a dynamic and functional analysis of social processes. In his 1894 textbook he had shown much interest in the social organism analogies that were so popular in the early period of sociology, but through his later work he became by far the most important American figure in promoting the recog-

nition and elucidation of the concept of the social process.

The basic raw material of the social process is, according to Small, group activities. Group activities tend to be based on elemental human interests, and the inevitable conflict of these interests provides the dynamics of the social process. This conception of Small's was first shaped by his reading of Marx and by his studies under Wagner and Schäffle which emphasized the economic pressures that produce social reconstruction. Small had also read the earlier books of Ludwig Gumplowicz, which stressed the conflict of social groups, but was repelled by Gumplowicz's naturalistic evolutionism, which maintained that mankind could not provide for the betterment of social conditions. Small believed that conflicts could be accommodated and anarchy prevented if the conflicts were carried out under the authoritative supervision of the state, which adjudicates group antagonisms.

As early as 1893 Small had constructed a comprehensive schedule of the human interests that emerge in comparable forms of group manifestations. While he was still developing this idea, he came into contact with *Wesen und Zweck der Politik* (1893), by Gustav Ratzenhofer, the learned Austrian general who was also a social philosopher. Small's attempt to fuse his own views with those of Ratzenhofer was already evident by 1903, and when he published his *General Sociology* (1905), the fusion was virtually complete. Although *General Sociology* is widely considered to be the mature expression of Small's doctrine of the dynamic role of the conflict of interests, many of his students contend that he presented the subject in a more complete and intriguing manner in his famous lectures on "The Conflict of Classes," which, unfortunately, were never published.

Small's contribution to sociological methodology, which he considered vitally important, has come to be virtually ignored, sociology has since turned toward a more quantitative approach. He was very concerned with defining the scope and objectives of sociology, outlining the main subdivisions of the field and stating its fundamental ethical goals.

Small made significant contributions to social science outside the field of formal sociology, especially to political science and economics. His conception of the state as the mediator of conflicting group interests inspired Arthur F. Bentley's famous *The Process of Government*, perhaps the most important American contribution to political theory in the twentieth century. Several of Small's books contributed to the development of institutional economics (1907; 1909; 1913; 1924). His

vigorous critique of the capitalist system was influenced not only by Marxism and the early welfare economists but also by his (temporary) Chicago colleague Thorstein Veblen and even more by Werner Sombart. It is not surprising that Small's wide-ranging acquaintance with the various social sciences should have led him, toward the end of his career, to be increasingly interested in promoting and encouraging their synthesis.

## SMITH, ADAM

Adam Smith (1723-1790) was born in Kirkcaldy, Fifeshire, a fisheries and mining town near Edinburgh. He was the son, by a second marriage, of Adam Smith, comptroller of the customs at Kirkcaldy, who died early in 1723. His mother, Margaret Douglas, was the daughter of a substantial landowner in Fifeshire. Smith lived with his mother whenever he was in Scotland until her death in 1784; he was her only child, and he remained a bachelor until his death.

Smith received his elementary schooling in Kirkcaldy and entered the University of Glasgow in 1737, graduating with an M.A. in 1740. He then went to Oxford University as a Snell fellow at Balliol College, where he stayed until 1746. Beyond the fact that at Glasgow he was a student of Francis Hutcheson, almost nothing is reliably known about his intellectual experiences either at Glasgow or at Oxford. From 1746 to 1748 he lived with his mother in Kirkcaldy, presumably continuing his studies and awaiting an opening for a career in some remunerative post. Between 1748 and 1751, under the sponsorship of some of the leading intellectuals of Edinburgh, he gave several successful series of public lectures, on rhetoric and belles-lettres, on jurisprudence, and perhaps on other subjects. On the strength of the reputation gained by these lectures, he was elected in 1751 to the professorship of logic at the University of Glasgow. When the chair of moral philosophy became vacant later in the same year, he was elected to that superior post, which he occupied until 1763. In 1759 he published his first book, *The Theory of Moral Sentiments*.

Early in 1764 Smith went to France as tutor of the young duke of Buccleuch, stepson and ward of Charles Townshend. Smith remained in France from early in 1764 until late in 1766, most of the time in Toulouse but for some months in Paris, where he saw a good deal of the leading physiocrats and philosophes. He also visited Geneva, where he made the acquaintance of Voltaire. After his return to England in 1766, he was until early in 1767 an adviser to Charles Townshend, then chancellor of the exchequer and working on his fatal plan for taxing the American colonies;

Smith's contribution to this plan, if any, is unknown. Endowed with a generous pension for life from the duke of Buccleuch, Smith returned in 1767 to Kirkcaldy, where he remained until early in 1773, working on *The Wealth of Nations*. From 1773 until early in 1776 he was again in London, completing the book but also advising the government occasionally on economic matters. On March 9, 1776, *The Wealth of Nations* was finally published, and soon thereafter Smith returned once more to Kirkcaldy. Early in 1778, he was appointed a commissioner of customs for Scotland and also a commissioner of the salt duties. These were not sinecure posts, as has often been alleged, but required his presence in Edinburgh for the greater part of each week throughout the year. For the rest of his life, he held these posts and lived in Edinburgh, where he died on July 17, 1790.

### Overview of writings

*The Theory of Moral Sentiments* and *The Wealth of Nations* were the only full-length books that Smith wrote; however, he kept revising both of them for successive editions, and the additions in the sixth edition of *The Theory of Moral Sentiments*, which was published only a few weeks before his death, were substantial in extent and importance. He contributed three essays to periodicals in 1755 and 1761, and a collection of essays on literary and philosophical subjects was first published posthumously in 1795 ("Essays on Philosophical Subjects" 1963). In 1896 Edwin Cannan edited and published a recently found student's report of Smith's economic lectures as given in 1763 at the University of Glasgow (*Lectures on Justice* . . . 1964). In 1963 John M. Lothian edited and published a student's report on Smith's lectures on rhetoric and belles-lettres at Glasgow in 1762/1763 (*Lectures on Rhetoric* . . . 1963), which he had shortly before purchased at an auction sale in Scotland. W. S. Howell, in an as yet unpublished manuscript, describes these lectures as "an important and original revolutionary document in an important revolution in the history of rhetorical theory," the "revolution" consisting of the substitution for the old rhetoric stemming from Aristotle and Cicero of a new rhetoric based on the new learning of Bacon, Descartes, Locke, and others. At the same auction Lothian also purchased a student's report of Smith's economic lectures at Glasgow. This report, which is now in the possession of the University of Glasgow, is substantially fuller and also, it has been stated, superior in quality to that published by Cannan in 1896. Smith is said to have lectured also at the University of Glasgow on nat-

ural theology. Shortly before his death he supervised the burning of almost all of his manuscripts, some 16 folio volumes.

Smith clearly had a wide range of interests. The evidence available suggests that he reached his basic methodological and philosophical principles early in his career and that his destruction of manuscripts before his death was probably motivated much more by dissatisfaction with their form or with their incomplete state than by any fundamental change in his views.

Almost everything Smith wrote, in its methodological implications if not in its concrete subject matter, has some relevance for social thought, but it is expedient here to concentrate on the two books he published during his lifetime. Many writers, including the present author at an early stage of his study of Smith, have found these two works in some measure basically inconsistent. But in much of his writing Smith worked from what he called systems and what today would be called models. He was aware that "systems" are incomplete in the factors they take into account. Had he been able to complete his total system, he would probably have demonstrated that the apparent inconsistencies were often not real ones, but were merely the consequences of deliberate shifts from one partial model to another.

In a letter of November 1, 1785, to a French correspondent, Smith wrote that he had "... two other great works upon the anvil; the one is a sort of Philosophical History of all the different branches of Literature, of Philosophy, Poetry and Eloquence; the other is a sort of theory and History of Law and Government. . . . But the indolence of old age, tho' I struggle violently against it, I feel coming fast upon me, and whether I shall ever be able to finish either is extremely uncertain" ([1785] 1896, p. 166). The manuscripts of these two "great works" presumably were among those destroyed shortly before his death.

### "The Theory of Moral Sentiments"

The first thing to note about *The Theory of Moral Sentiments* is its title. It is a "theory" or "system," that is, it consciously and deliberately employs some measure of patterned abstraction and thus does not profess to account for all the relevant facts of the real world. Its primary concern is only with that part of human psychology which is involved in the interrelationships of men living in communities—the "moral sentiments," that is, the passions, propensities, affections, feelings, whether of approbation or of disapproval, aroused by these interrelationships. These senti-

ments are intermediate, in degree of reflection or "reason" involved, between the basic instincts that man shares with the animals and the calculation or ratiocination of sophisticated man as a reasoning being. When and how and in what degree these sentiments operate Smith discovered through observation of his neighbors, and presumably also, although he apparently never explicitly said so, through disciplined introspection exercised on the assumption that men are substantially alike in their subrational psychology.

To show how the sentiments operate to socialize the individual, to fashion him into a disciplined member of a harmonious social group, Smith introduced into his model the concept of "spectators," distinguishing two main species. There is, first, the spectator external to yourself, the "real" spectator, who, by manifesting in some manner his sentiment of approval or disapproval of your behavior, exercises an influence on you. There is, second, the internal spectator, yourself, operating on two distinct levels: first, your imagination of what the reaction of a hypothetical external spectator would be to your actual or contemplated behavior, second, your own moral judgment, the judgment by your own conscience, by "the man within your breast," by the "impartial spectator." This whole complex mechanism of psychological response by men to their neighbors' feelings of approval or disapproval, which Smith called sympathy, he regarded as the major factor in creating and maintaining a socialized community. It involves, according to Smith, not only the desire to win the praise or approval of others but also the desire to be praiseworthy; when the two desires are in conflict, conscience decrees that the latter shall prevail.

Commentators have objected that Smith here described a circular process, operating through sympathy like a set of "mirrors," and that he failed to explain adequately either what behavior is approved and what is disapproved or the origin or genesis of the social passions. Yet, at least by implication, Smith did offer such an explanation. He emphatically rejected human reason as the source of these sentiments. Also by implication he denied that there is a natural evolutionary process in which groups with a pattern of sentiments that is predominantly useful survive, whereas those groups with a pattern of antisocial sentiments perish. Smith maintained that man is endowed by God with his moral sentiments and that these sentiments bind men to each other because the deity so made them in its concern for the happiness of mankind. Smith ridiculed those who attributed to man's wisdom what is really the wisdom of God,

or of nature. Here Smith was, of course, invoking "final causes," or "the invisible hand."

It is hard for some people today to believe that Smith's optimistic deism was completely sincere, and they tend to attribute his exposition of it to prudential considerations or to concessions to a mode of speech called for by the standards of propriety of the time. But in the "enlightened" Scottish circles of Smith's time optimistic deism, sincerely held, was practically universal. Although orthodox Calvinists rejected its optimistic aspect as not religious enough and David Hume rejected it as calling for too much religious faith, aside from Hume, no one among Smith's teachers, colleagues, friends, or followers is identifiable as a critic of optimistic deism.

There may be genuine difficulty in reconciling Smith's deistic interpretation of the origin of the moral sentiments with other aspects of his social thought, including some of his specifically economic thought. Smith attributed to providence the original endowment of mankind with a set of moral sentiments conducive to the happiness of mankind. But unless he also assumed that providence intervenes constantly or intermittently to make appropriate adjustments in these sentiments as the physical or human environment changes through time (for which belief there is no evidence in anything he wrote), Smith would seem to have been postulating a static social psychology, at least on the subrational level, in what he himself admitted to be in many relevant respects a constantly changing and evolving world. Smith did recognize the impact of the variability of custom and fashion on the mode of operation of the moral sentiments, but, in spite of this variability, he specifically recognized only one major historical affront to the system of moral sentiments—the prevalence of infant exposure in the later period of ancient Greek civilization. He disposed of this exception as a temporary aberration, outweighed by the many outstanding virtues of Greek civilization at the time. Nowhere did he attempt to explain how antisocial passions and aberrations in conflict with the "Author of Nature's" design came into existence. But in keeping with the notion then held by some scientists that there is in nature a self-equilibrating mechanism by which aberrations are prevented from prevailing, a notion having some analogy to the modern scientific notion of "homeostasis," Smith held that there is an inherent tendency in the moral sentiments to overcome such aberrations.

Smith's treatment of "justice" in *The Theory of Moral Sentiments* is especially important for a proper interpretation of *The Wealth of Nations*.

Smith always used the word to mean substantially what Aristotle and the Schoolmen meant by "commutative justice." Justice is a negative virtue; it consists of refraining from injury to another person and from taking or withholding from another what belongs to him. It is thus distinct from benevolence, friendship, or charity. Smith considered justice, so understood, to be the necessary foundation of a viable society. It is a moral sentiment and thus finds voluntary or natural expression. The natural or spontaneous sentiment of justice is not, however, strong enough in ordinary men to meet the needs of society. Consequently, men have been endowed with the propensity to formulate rules of justice on the basis of their experience and reason, and they accept these rules for themselves and press them upon others. But even this is inadequate for the needs of society, and therefore government is established, its chief function being the coercive enforcement of justice on the individual members of the community through law and the magistrates.

The moral sentiments operate at different levels of intensity according to the nature and the strength of the external stimuli impinging upon men. Smith's discussion here closely parallels Hume's discussion in *A Treatise of Human Nature* (1739-1740, book 2, part 2, especially sec. 4) and elsewhere: in describing the way in which the strength of the "passions" between individuals varies with the closeness of their relationship with respect to duration, space, kinship, nationality, occupation, rank, and so forth, Hume repeatedly used the term "distance" metaphorically to signify any factors separating individuals from each other, a usage that goes back at least to Aristotle and Thomas Aquinas. Although Smith stressed distance in its primary spatial sense as an important factor in weakening the intensity of the moral sentiments—"To what purpose should we trouble ourselves about the world in the moon? All men, even those at the greatest distance, are no doubt entitled to our good wishes, and our good wishes we naturally give them. But if, notwithstanding, they should be unfortunate, to give ourselves any anxiety upon that account seems to be no part of our duty" ([1759] 1966, p. 197)—he also used the same idea, if not the actual term "distance," for the absence not only of spatial proximity but also of membership in the same family, village, town, province, country, circle of friends, guild or company, church, social class, or some other psychologically unifying bond. In similar manner he took it for granted that the participants in a large number of the transactions which occur in the market are (in the metaphorical sense) at an extreme dis-

tance from each other; they are, in relation to each other, anonymous, or strangers, so that there is limited occasion for any moral sentiments other than justice to come into operation.

In *The Theory of Moral Sentiments*, Smith minimized the contribution that even the highly successful pursuit of wealth or of higher social status makes to the happiness of an individual. Both in this work and in *The Wealth of Nations* Smith treated increase in aggregate wealth as a highly worthy objective for a country, but apparently in only one passage in either work is increase in *per capita* wealth or income expressly mentioned as a reason for the advantage of an increase in aggregate wealth. Smith attached little importance to an increase above a quite modest level of *per capita* income, but he attributed great value to the increase of population that an increase in aggregate wealth fosters and supports. With his optimistic view of the amount of happiness ordinarily enjoyed even by the poor, Smith believed that growth of population is ordinarily conducive to growth in the aggregate amount of human happiness. He also found value in increase of aggregate wealth because it makes possible an increase in handsome buildings and great avenues in the towns, the "magnificence" so extolled by the writers of classical antiquity and of the Renaissance, but he treated these as public rather than individual riches. Smith also included as an advantage of growth of aggregate wealth the progress of aesthetic and intellectual culture and of "civilization" in general, which he associated with communal enrichment.

### "The Wealth of Nations"

*The Wealth of Nations* is of great importance for three main reasons. First, it presents an impressive collection of economic data, gathered together by Smith from wide reading in publications from the time of the ancient Greeks and Romans to his own time and from acute observation of Britain and France in his own time. Smith used this material to illustrate and support his analysis of contemporary economic process, to provide a factual basis for his frequent ventures into the philosophy or theory of economic development, and at times to digress into narrative history presented without any clear relationship to his theoretical endeavors. *The Wealth of Nations* was heavily drawn on as a reliable source book for factual data by several generations of writers on economic matters, especially, of course, in the English-speaking countries. It is still useful for this purpose.

Second, it was the most comprehensive and ambitious attempt up to Smith's time to present in

comprehensive, and at the same time coordinated, fashion the nature of economic process in a predominantly "individualistic," or "competitive," or "market," or "capitalistic" society, to use modern adjectives. For a long time it largely determined the selection of issues and the initial analytical approach of economists in many countries, even when in their treatment of *The Wealth of Nations* they were much more critics than disciples.

Third, it was an evaluating and crusading book, which sharply criticized existing society and government and argued strongly for changes in national policy, especially in relation to the extent and nature of government intervention in economic matters—domestic, colonial, and international. Not immediately, but within a generation, it became a powerful influence on writers on economic policy. Later still, both directly and indirectly through those influenced by it, it became a significant factor in determining the course of national policy not only in Britain but in other countries as well. This is much more than any other economic work has ever achieved; and Smith probably has had much more influence than any other economist.

**Economic development.** Smith was deeply interested in the history, the causes, and the natural and artificial limitations of what we now commonly call "economic development" and what he referred to as "progress," "improvement," "progress of improvement," and "progress of opulence." His treatment of economic development is scattered throughout almost the whole work. He put most stress on the following factors as favorable to economic development: abundance of natural resources; technological progress as promoted by extension of division of labor; freedom of private enterprise from its own propensity to monopolistic organization; freedom from such hurtful artificial institutions as primogeniture; and freedom from official policies and practices that act as brakes on individual initiative or misdirect it. The basic source of economic progress, however, he found in the striving of individuals to improve their economic status or their rank in society—"... the desire of bettering our condition, a desire which ... comes with us from the womb, and never leaves us till we go into the grave" ([1776] 1950, p. 323). He did not believe that this desire does or should operate without restraint. It is disciplined by the sentiment of justice and by governmental enforcement of justice. It has to compete, beneficially or otherwise, with "the passion for present enjoyment," which acts as a restraint on accumulation; with indolence; with the occasional "liberality" of

employers to their workmen and of landlords to their tenants; and with "the pride of man [which] makes him love to domineer," so that a plantation owner may prefer the service of slaves to that of freemen even where the latter would be more profitable. All of these are factors that are present in a different degree in different orders of society and in different circumstances. Smith, moreover, saw the desire for individual enrichment and the desire to preserve or improve one's social status as occasionally coming into conflict, as, for instance, when one's rank calls for profuse expenditure but the preservation or augmentation of one's estate calls for frugality.

Smith placed great emphasis on the division of labor as a requisite of economic development; he also stressed the interrelations of the division of labor with technology and with commerce. He found a subrational or nonutilitarian origin for the resort to specialization (although not for its intensification) in a "propensity to truck and barter" innate in mankind. Here, following certain predecessors, he identified three contributions that the division of labor makes to productivity: by permitting indefinite repetition of simple tasks, it promotes dexterity; it eliminates the loss of working time involved in changing from one task to another; it facilitates invention of machinery, both by the artisans on the job and by outside observers. Smith stated that extension of the division of labor makes more capital necessary and therefore makes frugality and accumulation economic virtues. He always minimized the differences of innate ability or aptitude between different persons and thus gave little or no weight to the advantage claimed for specialization by a continuous chain of writers from ancient Greece on—that it makes possible the assignment of workers to those tasks for which they have the greatest aptitude. Smith pointed out that the division of labor is limited by the extent of the market and that growth of population both constitutes an extension of the market and is made possible by the increase of aggregate production that results from an extension of the division of labor. Growth of population, growth of aggregate wealth and income, and extension of the division of labor are thus explained as mutually dependent and mutually supporting factors.

Smith recognized, under the influence of Rousseau, that the division of labor has a drawback from a humanitarian point of view: the worker as a person tends to be degraded by the monotony of his work and the enlistment of only a narrow range of his mental faculties. Smith thought, however, that this predicament could be remedied by educa-

tion. This is one of the reasons that Smith accepted as a desirable function of government the financing, at public expense, of elementary education for the children of the poor. Smith's discussion was cited by Karl Marx in his presentation of the thesis that a degradation or "alienation" of labor is a consequence of division of labor, but Marx was unaware of the prior treatment of the subject by Rousseau to which Smith was indebted.

Smith's belief that the tendency to aggregate improvement is "natural," i.e., essentially the product of man's basic psychology, may have been a factor contributing to his skepticism about the possibility that government may make major positive contributions to economic development. While he charged government in general with operating as a brake on economic progress, Smith nevertheless remained an optimist. In man's zeal to better his condition, the "wisdom of nature" had provided a counterforce to mistaken government policies and practices that was sufficiently powerful to make possible, in most cases, a thriving and prospering economy.

**Smith's eclecticism.** It is a common error to interpret *The Wealth of Nations* as an unqualified eulogy of private enterprise and the businessman. It was only private enterprise operating in a fully competitive manner that Smith praised. He depicted businessmen in general as having a constant propensity to organize themselves into groups capable of exercising "monopoly" power, groups to which he indiscriminately attributed the capacity and, by implication, the will to exact the highest price at which any sales can be made. He also charged businessmen with major responsibility for persuading or pressing government to establish special privileges and legal monopolies for favored groups. Where monopoly is unavoidable, he preferred government to private operation. He had only deep and violently phrased scorn for the morals of businessmen organized in groups either to operate as monopolists or to obtain special privileges from government. *The Wealth of Nations* does lavish praise on the businessman, but only when he is on his good behavior.

Smith's main merits as an "analytical" or "scientific" theorist, to use modern eulogistic terms for "pure" economic theory, lie in his eclectic spirit. While deliberately resorting to abstraction, he very much doubted that abstraction could provide either understanding of the real world or, by itself, safe guidance for the legislator or statesman. On specific points of economic analysis some predecessors did better than Smith, and he failed to absorb fully some of the genuinely valuable analytical

contributions of Hume, the physiocrats, and Turgot. If "analytical" as a eulogistic term is to be interpreted strictly in terms of degree of rigor, internal consistency, and close analogy to abstract mathematical operations, Schumpeter's verdict that "the *Wealth of Nations* does not contain a single analytic idea, principle, or method that was entirely new in 1776" (Schumpeter 1954, p. 184) is difficult to challenge, and not merely because valuable ideas that are "entirely new" are hard to spot in any area of intellectual endeavor.

In both his major works Smith repeatedly amended his system, bringing into his discussion some hitherto neglected variable, some fresh observation of fact, some new objective. He has been rightly charged by critics with resorting profusely to such qualifications as "perhaps," "generally," and "in most cases," with the consequence that his models are not tight or rigorous. It is arguable, however, by those who, if forced to choose, prefer realism, or at least the pursuit of it, to rigor and elegance of analysis, that both of his major works are on the whole made better by the qualifications he sprinkled in their pages and that he would have made them still better, although still untidier, if he had used even more qualifying adjectives or phrases. He would at least have made it harder for later critics to use short quotations, out of context or stripped of their qualifications, to show his inability to avoid flagrant self-contradiction.

The question of the relation of relative labor input to exchange value is one instance where Smith appears repeatedly to have shifted from one belief to another; however, it may be that actually he was only shifting from one abstraction to another, while decorating his exposition (in a manner common then and not unknown now) with traditional maxims exalting the role of labor—maxims whose familiarity alone made them seem to carry logical or empirical weight. Smith can be quoted in support of all of the following propositions: that labor is the sole "source" of market value; that labor is the sole regulator of exchange value; that labor has, among the elements entering into production, a peculiar and perhaps even an exclusive value-creating power; that the relative values of different commodities are, or should be, proportional to their labor-time costs or to their wage costs; that all incomes are extracted from the product of labor. For some economists any one of these propositions suffices to label its exponent a "labor theory of value" theorist. It seems safer, nevertheless, not to attribute to Smith much more than the belief that in commercial or capitalist economies relative labor-time costs per unit of product have a large part in

the determination of the exchange values of different commodities, and relative wage-costs even more.

**Economic policy.** The separation of normative from non-normative, or policy, economics was a late development in the history of economics, and even today it is hard to fully execute this separation because many of the standard terms used in economic analysis carry with them an almost automatic normative or evaluative implication: for example, "productive," "utility," "value," "equilibrium." Prior to Smith's time it was rare for any writer to attempt to distinguish between, on the one hand, the study of economics in the purely "scientific" sense of the pursuit of understanding for its own sake, and, on the other hand, the use of economic analysis as an instrument for the formulation or evaluation of national economic policy. (Richard Cantillon was one of the few who did make this distinction.)

When Smith wrote *The Wealth of Nations* the term "political economy" was already in wide use. It was used with some ambiguity, but predominantly with emphasis on "political," indicating reference to national policy. The term "economics" was rarely used by itself except in its original Greek meaning of household management. When Smith chose as the title of his book *An Inquiry Into the Nature and Causes of the Wealth of Nations* instead of something like "Principles of Political Economy," it may be surmised that he did so because he thought of his book as including both an objective study of processes and causes, such as would be the subject matter of a treatise on physics or physiology, and a discussion of "political economy" proper, or an evaluative or hortatory treatment of governmental economic policy. Smith used the term "political economy" a dozen or so times, and every time, except perhaps once, he meant the economic policy of a nation. Since Smith generally took a dim view of the benefits to be derived from national economic policy, political economy must for him have been nearly synonymous with "economic poison."

Smith, of course, was not an exponent of philosophical anarchism, which apparently had nowhere been systematically expounded before William Godwin's *Enquiry Concerning Political Justice* (1793). If Smith had adopted the term "laissez-faire" as an appropriate label for his own policy views, he undoubtedly would not have interpreted it literally as a condemnation of all government interference with the activities of private individuals. He was as emphatic as he could be on the vital need for government enforcement of justice,

and there is evidence in *The Wealth of Nations* that he would have included in this function not only the formulation of rules of justice and the provision of machinery for the punishment of their infraction, but also the prevention of certain infractions by such enactments as standardization of weights and measures, requirements that commodities offered for sale be so stamped as to indicate their quality, and the establishment of building standards that would hinder individuals from subjecting others to the risk of fire or to other hazards to their property or their personal safety. Smith assigned to government the care of the defense of the community against foreign aggression or internal disorder and the levy of taxes to finance these activities. He also conceded to government the provision of those services needed by the community which could not practically be entrusted to private enterprise, because of the scale on which they had to be carried out or for other special reasons. On at least two issues—a "standing" or professional army versus a militia and the autonomy of the East India Company—Smith expressed a strong preference for governmental control in addition to or instead of private management. In general, where monopoly was unavoidable, he much preferred that it be under public rather than private control.

Nevertheless, it is as an exponent of free enterprise; free trade; noninterference of government in the individual's choice of occupation, residence, or investment; freedom for the individual to make his economic decisions of all kinds in response to the price movements of free and fully competitive markets—in short, of "economic liberalism" or "laissez-faire," as these terms were used in the nineteenth century—that Smith made his chief mark on the history of economics and on the economic and social history of the Western world.

These economic freedoms were to Smith "natural rights," essential constituents of the dignity of man. He also valued them from a utilitarian point of view, as giving maximum scope for incentives to industry and to efficiency. In the international sphere he saw in them the most solid factors working to bring peace between nations. Modern economists find Smith's arguments oversimplified and perhaps also too emotional and one-sided. But many of them still acknowledge a strong influence of his writings on their system of values and gladly continue to do homage to his name.

## SMITH, WILLIAM ROBERTSON

William Robertson Smith (1846-1894) was born in Scotland, the son of a distinguished scholar and minister in the Free Church of Scotland. The father instilled in his son a love for learning and for free critical inquiry, especially in the field of Biblical studies.

While Robertson Smith was a student at the University of Aberdeen his main interest shifted to mathematics and physics, subjects that he never wholly abandoned. His work in these subjects, published while he was still in his early twenties, was well thought of, and many years later he was considered as a candidate for a chair of mathematics at Glasgow. However, his first published paper, entitled "Prophecy and Personality" (1868), derived from his Biblical studies, and it was this field that subsequently took overwhelming precedence. After his early training at Aberdeen he went to the New College seminary at Edinburgh. In 1870, when he was only 24 years old, he was appointed to the chair of Hebrew and Old Testament exegesis at the Free Church College at Aberdeen, and five months after this appointment he was ordained.

For six of the 11 years of his stay at Aberdeen, wrangles with the general assembly over the issue of Biblical criticism consumed his time and sapped his energies. Some of his lectures had aroused suspicion, but the matter came to a head with the appearance of his article "Bible" (1875) in the ninth edition of the *Encyclopaedia Britannica* and of a review of this article, ascribed to A. H. Charteris, professor of Biblical criticism at the University of Edinburgh, which accused Robertson Smith of importing discredited views from the Continent and of tarnishing a theological professoriate. The celebrated "Robertson Smith affair" had begun; thereafter he was hounded by the Free church, and rather than accept the odious limitations on intellectual activity that were the condition of his continuing occupancy of the chair at Aberdeen, he stood his ground and in 1887 was removed from his post. The two succeeding years were devoted almost entirely to writing articles for the *Encyclopaedia Britannica* and to the enormous amount of editorial work he undertook as its chief editor—it is said that he read the entire edition.

During the struggle with the governing body of the Free church, Robertson Smith had been offered two appointments by Harvard University: first, the chair of Hebrew and Oriental languages and, later, the chair of ecclesiastical history. He did not accept either, but in 1889 he was offered the chair of Arabic at Cambridge and accepted with great pleasure. He found time amid his academic activities to make several visits to Egypt, and on one of these he accompanied the celebrated explorer Richard Burton on a minor expedition. He spent two months in Arabia; he traveled in Palestine, Syria, and the Libyan desert; and during another period of leave he went to Tunisia and Algeria. He made his way easily among the Arabs and recorded some of his observations, but he lacked the time and the training for any systematic studies of social life.

Several influences contributed to Robertson Smith's intellectual development. His home environment encouraged the study of Hebrew, Arabic, and the classics, and he shared the interest in history and in the nature of human progress that was characteristic of the general Scottish intellectual environment. The latter preoccupation had produced in the eighteenth century a group of philosophers who were deeply curious about the evolution of social institutions (Bryson 1945). More directly, Robertson Smith was influenced by his friend J. F. McLennan, a Scottish barrister and the author of *Primitive Marriage and Studies in Ancient History*. McLennan, in turn, was familiar with the work of Fustel de Coulanges who, in *The Ancient City*, had functionally related the development of religion (from its classical roots to the appearance of Christianity) to the kind of social units into which people were arranged, although he did give religion a sort of causal priority in producing social change. [See the *biographies of McLennan and Fustel de Coulanges*.] An examination of Robertson Smith's general theories of religion clearly reveals how profoundly these ideas influenced him.

The two works of Robertson Smith's that were important for the development of sociology are *Kinship and Marriage in Early Arabia* (1885) and *Lectures on the Religion of the Semites* (1889). Of the two, the analysis of religion has had the greater influence, but its full understanding requires a knowledge of some of the ideas about tribal society in the analytically weaker book on kinship. In fact, the two works go hand in hand. (The very first formulation of Robertson Smith's general views on religion appeared in the well-known article "Sacrifice" in the ninth edition of the *Encyclopaedia Britannica* in 1886, a few months after the study of kinship.)

### Analysis of religion

As a churchman and theologian, Robertson Smith had an immediate concern with religion. His writings were, in part at least, the solution to a personal problem, giving him a more satisfactory understanding of the essence of religion and a reason for his continued convictions. It is only in the light of his commitment to religion that his long and acrimonious struggle with the Scottish Free church makes sense, for his aim was to help revitalize religion, not to destroy it.

His penchant for looking at things sociologically led him first of all to the problem of a satisfactory analysis of beliefs. His point of analytical departure was to argue that the beliefs people hold and the general dogmas to which they subscribe are not acquired by individual effort—that is, they are not a matter of individual choice resulting from reasoned argument but are part of the general social apparatus with which man is endowed at birth. Religion is a part of an individual's collective representations, to use the phrase Durkheim later introduced into sociological vocabulary. In other words, Robertson Smith saw religion as "a part of the organised social life into which a man was born, and to which he conformed throughout his life in the same unconscious way in which men fall into any habitual practice of the society in which they live" ([1889] 1927, p. 21). Thus gods and their worship are taken for granted, just as other usages are accepted, and "if they [men] reasoned or speculated about them, they did so on the presupposition that the traditional usages were fixed things behind which their reasonings must not go, and which no reasoning could be allowed to overturn" (p. 21).

Early religion, according to Robertson Smith, had very little to do with beliefs; it was concerned with practices, and conformity was a matter of course. Just as in studies of political structure, an inquiry does not begin "by asking what is recorded of the first legislators, or what theories men advanced as to the reason of their institutions" (p. 21), but by seeking to understand political institutions and their effect on social relations, so too the study of religion must be directed at "the workings of religious institutions" and the way in which the relations of the worshipers are shaped. The analogy is not arbitrarily chosen, for, Robertson Smith contended, "the parallelism in ancient society between religious and political institutions is complete" (p. 20).

Robertson Smith believed that political institutions are older than political theories, and in the same way, religious institutions are older than re-

ligious theories. Rites are prior to beliefs, rationalization follows practice. There is evidence for priority of ritual in early forms of religion, which were constituted wholly of ritual and practical usage. Practices that persist do tend to acquire accretions of explanatory beliefs, but the meanings thus attached are inconsequential, vague, or contradictory, while the practices are fixed. More often than not, people are unaware of the doctrinal differences that divide sects in the contemporary world, and when doctrinal explanations of ritual acts are given at all, these may differ within the same religion and culture without any question of orthodoxy being raised; conspicuously less leeway is permitted in the carrying out of proper procedures. Robertson Smith felt that sociological inquiry would do well to begin not with a creed or with what individuals privately think but with overt ritual acts. Some sixty years after Robertson Smith had made this point with crystal clarity, Radcliffe-Brown was still laboring it thus: "My suggestion is that in attempting to understand a religion it is on its rites rather than beliefs that we should first concentrate our attention" (1952, p. 155).

Robertson Smith's study of ancient religion led him to conclude that it is external religious acts that give religion its principal social meaning. In ancient society, the rites of religion ensured conformity: privately, a man might believe what he liked; only by public acts of piety was it possible to judge whether he subscribed to religion. It was through his acts that the participant revealed his social identity, and for this identification his beliefs were virtually irrelevant. Further, acts and ritual were necessarily rigid because they showed public conformity and were testimony of a person's social outlook. Nonconformity, therefore, meant that someone was at odds with his social group. Ritual was the discipline that ensured the cohesion and continuity of social groups. Performance of rituals pledged continued membership in a social group; default was a public withdrawal. Excommunication was in fact the severance of ties to a social group and was therefore the same as outlawry. Religious allegiance and political connection were one and the same thing; a change of one was a change of both. Alter a man's political status and he is compelled to change his religion, "for a man's religion is part of his political connection" ([1889] 1927, p. 36).

Viewed in this light, ancient religion had both regulative and stimulative functions. It was regulative in the sense that the welfare of the individual could reach its optimum development only to the extent of his compatibility with his fellowmen. Individual goodness, it follows from this, was the

behavior that made for the general harmony of the community. By the same token, sin was an act that seriously disrupted this internal harmony and produced an impasse in relations, leading to the kind of stultification that could be remedied only by excommunication from the religious congregation and by outlawry from the social group. Religion, however, was not merely regulative in the sense that it compelled conformity; it was also stimulative, in that ritual was a repetitive statement of divine and human unity. Each and every religious act revived and consolidated the community of worshipers, giving it a consistency of purpose and a continuity of being. Religion was a social activity from which the good of the community was derived. "Religion did not exist for the saving of souls but for the preservation and welfare of society . . ." (*ibid.*, p. 29). Religion was based on these two elements—the regulative and the stimulative—rather than on personal problems of redemption.

In his writings on sacrifice, Robertson Smith further analyzed the nature of the congregation of worshipers, which he regarded as "the central problem of ancient religion . . ." (p. 27). He rejected the several theories of sacrifice—gift, tribute, covenant, expiation, propitiation; indeed, he could hardly do otherwise, given his acceptance of the premise that religion is a social activity, because this premise implies that the *intentions* of the sacrificer are relatively unimportant. Instead, Robertson Smith focused his attention on those who participate in the sacrificial act by partaking in the commensal meal. He rejected the view, recently endorsed by Evans-Pritchard, that the festal meal which succeeds a sacrifice "is not a sacramental meal but an ordinary commensal act of family or kin which, moreover, falls outside the sacrificial rites" (Evans-Pritchard 1956, p. 274). The greater part of one chapter in Robertson Smith's *Lectures on the Religion of the Semites* (especially pp. 272–282 in the 1927 edition) was devoted to the argument that the meal succeeding the slaughter was *not* a mere family affair but was eaten by a congregation of worshipers. Today also, as the present author's studies show, it is not permitted among the Bedouin Arabs for one family alone to consume the flesh of a slaughtered domesticated animal.

Robertson Smith pointed out that the meal following a sacrifice further differed from an ordinary meal in two ways. First, the flesh of the sacrificial victim was *meat with a special status*, different from the meat of game. (Again, this is a distinction drawn also by contemporary Bedouins. When game—gazelle, for example—is captured, the captor may distribute it among the households in a camp

as a matter of generosity, or he and his family may consume it entirely, running no more risk than the charge of meanness.) A commensal meal, therefore, is not simply an arrangement by which people who happen to be at hand join in eating but one at which attendance is obligatory because the meat is that of a sacrificial animal. Confusion sometimes arises around this point because all animals are customarily slaughtered in a prescribed manner. But ritual slaughter does nothing more than make it permissible to eat the flesh; it does not command a congregation and must not be confused with an act of sacrifice. Whether or not the flesh provides a commensal meal depends on the status of the animal and its relation to the person who slaughters it or who has it slaughtered.

Second, the special character of the commensal meal following a sacrifice was related to the link between the owner of the slaughtered animal and the victim: the victim was part of the sacrificer in a very intimate sense. This is also true among modern Bedouins: a camel or a sheep is part of a man's *risiq* (wealth) in the same way as are his children, and they are frequently and affectionately referred to by the same word. The host who slaughters one of his own animals is offering something of himself—a part of his "spiritual essence," which creates "a sort of spiritual bond," as Mauss put it—and all those who accept are thereby accepting a special relationship with the host, based on commensal nourishment. They become men who have joined together to share their economic resources for the common preservation of their lives.

Robertson Smith maintained that eating together constituted a bond among men equivalent to kinship. Participants in the meal, regardless of their consanguineous connections, were men bound by mutual obligation (another way of saying "kinship") sealed and covenanted in God. For kinship, as Robertson Smith saw it, was a matter not of consanguinity but of defined social relationships. Shrewdly, he pointed out that the tie that united the foster child to his foster mother and her kin was a tie of milk, not blood ([1889] 1927, p. 274): closeness of kinship was established not by birth but by nourishment. The sacrificial meal was one that a man shared with his commensals, "so that commensality can be thought of (1) as confirming or even (2) as constituting kinship in a very real sense" (p. 274).

Thus, in the early history of religion, the important relationship was not that of the individual man to a supernatural power, but that of "all the members of the community to a power that has the

good of the community at heart . . ." (p. 55). Communities were small, and the rivalry between them was expressed through the gods of the communities, just as the rivalry between neighboring villages in Spain is expressed through their local saints (p. 31). "Solidarity of the gods and their worshippers as part of one organic society" (p. 32) kept groups of people apart. As society advanced and institutions were elaborated, religious organization developed in matching likeness. With the fusion of groups into larger unities, political growth was marked by the appearance of a hierarchy of new gods: "A society and kinship of many gods began to be formed, on the model of the alliance or fusion of their respective worshippers" (p. 39). Church organization and political divisions were but two aspects of the same thing. This part of Robertson Smith's argument clearly shows the influence of Fustel de Coulanges, whose theme in *The Ancient City* was the parallel development of religious and political organizations.

Durkheim, whose writings on religion have had much more general influence than those of Robertson Smith, later argued that social groups possess stability only if a sentiment of unity exists, which must be given collective expression in emblematic form; and through this emblem, society worships itself. This view is an elaboration of what Robertson Smith wrote, for like Durkheim, he saw in the unity of the social group the core of religion. Since the whole edifice of religion is built up out of the unity that exists in groups, from the smallest to the largest, the idea of God is rooted in the local community and its growth is the elaboration of political organization.

This general idea was accepted among social scientists until Evans-Pritchard—first in an article on Nuer sacrifices (1954) and then in his book *Nuer Religion* (1956)—put forward a fundamentally different interpretation. Although he admitted what he called a structural role for religion—that there is a relationship between the various spirit manifestations of God and the points of division in a political system, since people who live together will worship together—he asserted that God stands outside the society altogether and that his various manifestations in society are only refractions of the external God. This is the idea of the one and the many, so brilliantly treated by Johnson (1942). For Robertson Smith, the notion of God was the notion of social unity, which grew as political organization developed; God stands at the apex of a hierarchy of social groupings. For Evans-Pritchard, God does not grow out of the social structure and is not limited by it. Robertson Smith and Evans-

Pritchard are not simply two scholars with disparate opinions on a limited, specific problem. They represent two ways of looking at human life between which there is no possibility of compromise: Evans-Pritchard attaches basic importance to what men think, while Robertson Smith attaches similar importance to what men do, and each scholar observes and weighs the evidence accordingly.

### Kinship and marriage

The second major work of Robertson Smith's that is of importance to modern sociology is *Kinship and Marriage in Early Arabia* (1885). Much of this work is marred—indeed is rendered virtually profitless in parts—by his preoccupation with the stages in the evolution of marriage and with an attempt to demonstrate that kinship was reckoned in the female line before precedence came to be given to male descent. The influence of his friend McLennan on his thinking in this field of study was an unmitigated misfortune. It led Robertson Smith to indulge in wild speculations, which he tried to support by guessing many of the facts. However, when he used authentic data, he did make a number of astute points.

Early Arab society was divided into political groups based on genealogical descent lines, reckoned through males. Robertson Smith did not concern himself with arid verification or refutation of the validity of genealogies. Instead, he was quick to grasp the significance of the consistency between the branching of genealogical lines and the political divisions of tribes. This consistency meant, he said, that the genealogies were manipulated to suit the reality of political divisions and that this was done by altering the length of descent lines to give groups of equal political status equally long descent lines ([1885] 1903, p. 11). Further, he showed some appreciation of the political processes (later to be known as fission and fusion) whereby tribal segments came together to form sections in opposition to like sections, only to dissolve into their separate parts when the situation provoking the combination ceased. His way of putting it was that several groups combined to form a larger whole, "resolving again into their elements" (p. 2). It is to his credit also that in his examination of the processes of alliance and opposition he noted that the occurrence of female names was indicative of greater cohesion in societies where descent was in the male line and polygamy was permitted: female names served to distinguish between paternal half-brothers and thus provided an additional divisive element in

simple patrilineal descent. After offering this interesting idea, however, Robertson Smith abandoned it and used the occurrence of female names as "proof" of an earlier system of kinship through women.

The crux of the problem of tribal organization, as Robertson Smith saw it, lay in the composition of the smallest political groups, out of which the larger ones were built (p. 3). Essentially, these were local communities whose constitution rested on the herding necessities of groups of people moving about, together with their animals, and controlling their own natural resources in water and pasture (p. 41). Robertson Smith conceived of each of these groups as a kindred and, while he rightly saw that consanguineous agnation was relevant within this group but not in larger ones, he also seized the important point that the smallest group was not merely "the family grown large" (p. 5)—that it was a political group and therefore quite unlike a family.

Idiomatic expression in ancient times gave the impression (and still does among Bedouin Arabs) that small political groups were composed of members of a kind of big family. Robertson Smith perceived that terms which appear to mean blood connection may refer to actual consanguineous relationships, or they may be used in the sociological sense of conceptualizing a unity. Thus when phrases such as "one blood" were used to refer to a group or when it was said after the loss of a member through homicide that "our blood has been spilt," it is erroneous to infer that all members of the group were consanguineously related (p. 46). Robertson Smith urged that discussions of kinship be divested of sentimentality and that categories of kinship be regarded not in terms of physiological connections but rather in the more meaningful terms of the duties and obligations which they symbolize. A father, in this sense, is the person who carries the obligations of protector, guardian, and provider of food. In ancient Arabia (and among the present-day Bedouins also) these obligations were acquired by virtue of the payment of bridewealth, as agreed to prior to the marriage contract. This transfer of wealth gave a man procreative rights to his spouse—"what he purchases is the right to have children by her and to have these children belong to his own kin" (p. 130). And further, he acquired the right to delegate the act of procreation to another man without losing his legal relationship to the children born to his wife—hence the saying, "the son is reckoned to the bed on which he is born" (p. 139). If consanguinity did not matter in this close relation-

ship, then obviously it was largely irrelevant when more distant relationships were involved. Kinship, in other words, was a matter of social relationships.

If relationships, then, are to be understood in terms other than those of consanguinity, it is necessary, Robertson Smith suggested, to look at the rights attached to each category. Thus, it would be profitable to regard the family as a property-owning unit, and the delimitation of this particular "kinship unit" would be the range of heirs (pp. 162 ff.). In analyzing marriage, his stress was similar: "Marital rights are rights of property which can be inherited . . ." (p. 105). Leach, writing three quarters of a century later, created something of a stir when he began his analysis of a Singhalese village with the assertion: "Kinship as we meet it in this book is not 'a thing in itself'" (1961, p. 11). He ended his analysis with the same statement, devoting the intervening pages largely to showing that kinship is nothing "except in relation to land and property" (p. 305). (This reductionist argument is discussed in Peters 1963. The composition of local groups among Bedouins, along lines not unlike those suggested by Robertson Smith in his book on kinship, is analyzed in Peters 1965.)

The tribal group of men that Robertson Smith conceived as a kindred was in fact a corporation. Equal responsibility was the privilege of all its members, regardless of the particulars of real or fictive kinship relationships. A group was "a single life" ([1885] 1903, p. 46) and indivisible. It possessed a unique name, leaving no doubt about a person's identity (p. 26), and it had rules of recruitment (pp. 40 ff.). Each corporation had a homeland with its own natural resources (p. 41). It also possessed the reproductive facilities of women (pp. 132-145). Control over its mobile property was achieved by disinheriting women (p. 117) who, had they been permitted to transmit property, could, by marrying outside the group, alienate its property. The corporation had authority to compel its members to accept stated obligations and to outlaw them in case of default (pp. 25, 27). In conclusion, the corporate group, to be effective, required members to be coresidents; since the most impelling obligation of membership was participation in offense and defense, it was necessary to be able to rally members in one place at short notice. Thus, corporations were local communities with a high concentration of agnates.

Later inquiries into the nature of tribal systems in ancient Arabia led Robertson Smith increasingly to ascribe importance to the institution of the

blood feud. There are references to the blood feud in his published works, but the notes he left were too fragmentary to form the basis of a complete analysis; his premature death robbed us of what would surely have been a brilliant work.

E. L. PETERS

## SMOKING

Tobacco was introduced to Europe by Columbus upon his return from the New World. As the habit of smoking spread throughout Europe, Russia, Africa, and the Orient, it met with formidable opposition from rulers, who instigated periodic attacks upon it. In 1604, King James I of England issued a proclamation called "A Counterblast to Tobacco." He and others, however, were unsuccessful in eradicating the use of tobacco, which soon became an export of considerable economic importance to the new American colonies. In the United States tobacco remains economically important; it contributes to national income, and its yield of tax revenue plays a significant role in the budget of the federal government.

Although social and religious controversies occasionally have flared between those segments of society which found smoking pleasurable and those which believed it to be a foul-smelling, unnatural, and loathsome habit, scientists showed little interest in the effects of smoking for some five centuries after its introduction to Europe.

In 1900 vital statisticians reported an increase in the incidence of cancer of the lung. Beginning in 1930, scientists from various parts of the world have reported vital statistics suggesting a relationship between certain populations' increasing consumption of cigarettes and an increased incidence of lung cancer, heart disease, and other illnesses in the same populations. Since the mid-1950s these results have become sufficiently convincing to cause the following health agencies to declare that smoking is a significant health hazard: the British Medical Research Council; the cancer societies of Denmark, Norway, Sweden, Finland, and the Netherlands; the American Cancer Society; the American Heart Association; the Joint Tuberculosis Council of Great Britain; and the Canadian National Department of Health and Welfare. However, cigarette manufacturers have steadfastly maintained that the evidence linking cigarettes and disease is not conclusive.

In any study of smoking, an initial problem arises with regard to the definition of who is a cigarette smoker and, even more problematic, who is an ex-smoker, light smoker, medium smoker, or heavy smoker. There is no precise definition as to what are the actual behavioral (motions), physiological, or psychological referents of smoking. For example, do all individuals who "smoke heavily" inhale to the same extent? One individual might light 40 cigarettes a day but puff only one-eighth of each, whereas another individual, claiming to smoke only 12 cigarettes a day, could inhale each of these down to the last quarter inch. We also do not know the relationship between reported smoking (through verbal self-report or responses to a questionnaire) and actual smoking. Data relevant to these preliminary questions would contribute greatly to the precision of subsequent research on smoking.

Within the past decade social scientists have become interested in the smoker, as evidenced by the appearance of numerous surveys and other research reports on the psychosocial characteristics of smokers. The vast majority of these have focused only on cigarette smokers, and the findings reported below will relate primarily to them.

The reader interested in a detailed review of

this subject may consult five reviews that include comprehensive bibliographies of the original literature. Two of the reviews appeared in 1960—one in the United States (Matarazzo & Saslow 1960), and one in Scotland (Kissen 1960). A third review was published by Lawton (1962) and a fourth by Horn (1963). The most recent review (Hochbaum 1964) was prepared as part of the highly publicized report of the advisory committee to the surgeon general of the United States Public Health Service.

Several individual studies are of especial significance because of their scope, sampling, or over-all design. Haenszel, Shimkin, and Miller (1956) surveyed the smoking habits of a cross section (40,000) of the total population of American men and women 18 years of age and older. Sackrin and Conover (1957) followed this by further study of 18,000 of the same 40,000 individuals. Kallner (1958) studied the entire population of Israel. Lilienfeld (1959) studied 4,400 adults in Buffalo, New York. Horn and his associates (1959) polled the total population of high school students (22,000) in Portland, Oregon, while Salber and her associates (see Salber & MacMahon 1961; Salber et al. 1962; Salber, Welsh, & Taylor 1963; Salber & Worcester 1964; Salber et al. 1961; 1963) have published a series of related studies of 6,810 high school students in Newton, Massachusetts. In England, Bothwell (1959) conducted a study of the smoking habits of 8,314 Oxfordshire schoolchildren, while Chave and Schilling and their associates (1959) studied another group of 3,500 London youngsters. Also, Eysenck and his co-workers (1960) attempted to measure some personality characteristics of a stratified sample of 2,360 smoking and nonsmoking adult British males and followed this with a more detailed study of 3,194 additional males (Eysenck 1963).

**Demographic variables.** Although social scientists have only recently begun to study the cigarette smoker, there already seem to be a number of variables which are consistently found to be associated with smoking. These variables are reviewed below, although, because of space limitations, no attempt has been made to review the findings of every study on each variable. Rather, the more significant or better-established findings of a particular study have been presented, and the original articles can be referred to for more detail. The reader interested in the attempts of health educators and social scientists to understand why people smoke and in some of the methods currently being explored in the United States to help smokers give up their habit should consult the report by Mausner and Platt (1966).

**Age, sex, and marital status.** With respect to age, data from both sides of the Atlantic are similar and indicate that regular smoking usually begins in mid-adolescence to late adolescence, although a small percentage of youngsters start cigarette smoking earlier. Boys are inclined to smoke somewhat earlier and more heavily than girls (Bothwell 1959; Cartwright et al. 1959; Haenszel et al. 1956; Hochbaum 1964; Horn et al. 1959; Horn 1963; Kissen 1960, p. 368; Matarazzo & Saslow 1960; and Salber et al. 1961). Among women, the incidence of smoking is increasing. In their study in Newton, Massachusetts, Salber and Worcester (1964) report that the number of women, particularly Jewish women, who smoke may soon exceed the number of men who smoke.

Among both sexes and all ages, there is a greater percentage of smoking among divorced and widowed individuals than among those either married or never married. Although this has been established for the United States, comparable data for other countries are not available.

**Income, occupation, and education.** The five reviews suggest that yearly income is not related in any consistent manner to smoking. However, socioeconomic class, when defined only in terms of occupational and educational level, does appear to bear a consistent relationship to smoking; individuals at the lowest occupational levels start to smoke earlier and in greater numbers than those in all other groups. For example, white-collar groups (professional workers, managers, and so forth) typically contain fewer smokers than are found among craftsmen, foremen, salespersons, and similar groups. Possibly it is because some individuals in the latter groups have higher yearly incomes than do some white-collar workers that the relationship between smoking and socioeconomic class, more broadly defined to include income and place of residence as well, is not clearly established.

Apparently there is no clear linear relationship between the highest educational level attained by maturity and smoking (see especially Lilienfeld 1959). However, among high school students those with highest achievement and those in college preparatory courses are considerably less likely to smoke than those in business and technical courses. An interesting twenty-year longitudinal study of a group of Harvard undergraduates indicates that individuals who major in the arts and letters, education, and social sciences later become smokers in greater numbers than do students whose career choice is in the physical sciences (Heath 1958; McArthur et al. 1958).

*Urban-rural differences.* In all studies examining urban-rural differences, rural farm populations, including both sexes and all ages, were found to contain a smaller percentage of smokers than either the rural nonfarm or the city populations. Rural nonfarm persons closely resemble urban dwellers in their smoking habits. Women and girls in large cities in the northeastern United States (e.g., New York City and Boston) smoke more than do women and girls in cities in other areas of the United States. It is unknown whether a similar pattern prevails when cosmopolitan centers such as London, Paris, and Rome are used as a basis for comparison.

*Race and religion.* In the English-speaking countries which have been studied, there appears to be no relationship between race and smoking, the proportion of smokers being approximately equal between the Caucasian and Negro subsamples.

It is well known that devout followers of some religions do not smoke at all (e.g., Hindus, Muslims, Mormons). Studies of young men and women of high school and college age in the United States (Horn et al. 1959; Salber & Worcester 1964; Straits & Sechrest 1963) have reported that significantly more followers of the Roman Catholic and Jewish faiths were found to smoke than Protestants in these age groups. In the Newton, Massachusetts, study, Salber and Worcester (1964, p. 36) found that Catholic men and boys smoked more than other males, while Jewish women and girls smoked more than other females.

*Psychological variables.* In addition to sociological and demographic variables, some psychological variables have also been explored.

*Intelligence and achievement.* Present available evidence suggests that there is no direct relationship between intelligence, as measured by tests of IQ, and smoking (Matarazzo & Saslow 1960; Hochbaum 1964).

The same is not true for academic achievement during adolescence, however. The previously mentioned studies in Portland, Oregon; Buffalo, New York; Newton, Massachusetts; and a study in London, England (Davis, as reported in Kissen 1960, p. 369) indicate that those students who are academically inferior to their age mates or classmates have a significantly greater tendency to be smokers. This relationship between achievement and smoking, of course, does not establish that one of the two factors is a cause of the other. It can be stated, however, on the basis of consistent evidence, that groups of young men and women who are academically less successful than their

peers contain a higher proportion of smokers than is found among their more successful classmates. Also, smokers are found to take the scholastically less demanding academic programs (vocational preparation in contrast to a college preparatory curriculum). Smokers date more but engage in fewer extracurricular activities, including sports of some types, than do nonsmokers. No interpretation of these disparate facts has yet achieved wide acceptance.

*Personality.* Studies attempting to relate personality variables to smoking suffer from the serious handicap that there exists today no highly valid, universally accepted measure either of global personality or of any specific personality dimension. (This assertion quite probably will find support among serious students of personality.) One result is that seldom do any two studies, even those allegedly measuring the same trait (e.g., neuroticism), utilize the same methods of assessment; therefore they cannot be compared meaningfully.

Matarazzo and Saslow (1960), Kissen (1960), Lawton (1962), Horn (1963), and Hochbaum (1964) have presented reviews of the few published studies in this area. The results, meager and poorly supported as they are, suggest the following. In most English-speaking countries roughly half of the population are smokers. Studies using stratified as well as nonstratified samples (some small, some large) reveal the presence of a slightly higher number of "extraverts" and "neurotic," "anxious," and "tense" individuals among the smokers as compared to the nonsmokers. However, although the differences in the mean scores of smokers and nonsmokers are statistically significant, they typically reflect a difference in response to only one or two questionnaire items. Two of the most extensive (3,194 individual subjects) and best-designed studies on this subject (Eysenck et al. 1960; Eysenck 1963) utilized stratified samples of individuals in the British Isles. In the second one Eysenck (1963, pp. 114-115) concludes: "Degree and type of smoking are . . . related to extraversion, in the sense that pipe smokers are introverted, as are non-smokers; light, medium and heavy smokers are extraverted, increasingly so in that order." The degree of extraversion among ex-smokers is found to be indistinguishable from that among light smokers. Such a strong conclusion may not be justified, however, since the mean extraversion scores, on the 31-item extraversion measure used by Eysenck, were as follows for the groups studied (in the order in which they are mentioned above): 17.07, 17.63, 17.60, 18.70, 18.95, and 17.71. Although several of the groups

differed significantly from each other because of the large number of subjects, the mean difference between the highest and lowest groups was only 1.88 items on the 31-item personality measure. Similar small but statistically significant differences between smokers and nonsmokers have been found on the "anxiety" scale used by Matarazzo and Saslow (1960, p. 499) and on the "tension," "psychosomatic," and "neuroticism" measures used by other workers.

Referring to the research described above in their 1960 review, Matarazzo and Saslow concluded

. . . while smokers do differ from non-smokers in a variety of characteristics, none of the studies has shown a single variable which is found exclusively in one group and is completely absent in the other . . . [this] is especially true for the variables measuring personality characteristics. . . . Examination of the means, standard deviations, ranges, percentages, etc. . . . makes clear that while group trends suggest the smoker to be more "neurotic," *on the average*, there are still many individual smokers with neuroticism, or anxiety . . . scores lower than those of many non-smokers. . . . Thus, a clear-cut smoker's personality has not emerged from the results so far published in the literature. . . . It is hard to believe that they [the half of a country's population who smoke] would share in common one personality "type." This is not to imply, however, that the various psychological dimensions along which smokers have been shown, as a group, to differ from non-smokers may not suggest an important single process, or processes, underlying these various demonstrated (but small) differences. Further research may indeed so systematize the disparate findings. (1960, pp. 508-510)

Thus, a number of studies report small differences in mean scores, suggesting that compared to the nonsmoker the average smoker has a slight tendency to be more extraverted, outgoing, adventurous, tense, anxious, inclined to drink more alcohol and coffee, date earlier, watch more television, see more movies, drive an automobile earlier, read fewer books per month, play fewer sports, and belong to fewer clubs and school organizations. However, a large number of individual smokers may show few or none of these characteristics. In addition, no unifying theme, trait, or personality dimension has been abstracted from these separate characteristics. For the present it seems best to conclude that any psychological dynamics that may differentiate the smoker from the nonsmoker have not yet been isolated.

**Initiation of smoking.** Phanishayi (1951), in India, was one of the first to study variables associated with the initiation of smoking. His research

was followed by that of McArthur and his associates (1958) with Harvard College undergraduates in Boston; Bothwell (1959) in Oxfordshire, England; Chave, Schilling and their associates (1959) in London; Horn and his associates (1959) in Portland, Oregon; Cartwright et al. (1959) in Edinburgh, Scotland; Morison and Medovy (1961) in Winnipeg, Canada; and Salber and MacMahon (1961) in Newton, Massachusetts.

These studies consistently have identified parental smoking as one of the most important predisposing factors in smoking among school-age children. As mentioned above, most smokers appear to have begun smoking between the ages of 10 and 18. If both parents smoke, the probability that their children will begin to smoke is several times that of children with nonsmoking parents. When only one parent smokes, the incidence of smoking among the offspring falls midway between that of the other two groups. Published data also suggest a higher frequency of smoking among children with older siblings who smoke.

The relationship of some other sociopersonal factors to initiation of the smoking habit is less clear-cut. In general, the studies suggest that youngsters' beginning to smoke is related to: (a) curiosity about smoking; (b) conformity pressures among adolescents; (c) need for status among peers, including self-perceived failure to achieve peer-group status or satisfaction; (d) the need for self-assurance; and (e) striving for adult status (see the reviews by Hochbaum 1964; Horn 1963). However, it is difficult to measure the strength of such needs, as well as their relative influence, and therefore these relationships should be considered tentative.

There is no convincing evidence that beginning to smoke in childhood or young adulthood is a sign of rebellion against parents or other authority figures, although such a hypothesis has been suggested by several writers.

Most writers have suggested that once the smoking habit has been established the factors associated with its continuation very likely are different from those associated with its initiation. Although the evidence is far from conclusive, it appears that situational tension-reduction is an important motivational factor in perpetuating the smoking habit. Also, a small group of smokers attest that they continue to smoke because it is pleasurable.

Many smokers report considerable dissatisfaction with smoking but, despite repeated attempts, have found themselves unable to break the habit. In fact, Horn (1963, p. 364), who sampled the adult popu-

lation of the entire United States, reports that only 14 per cent of regular cigarette smokers state that they consider the habit pleasurable, safe, and worth the cost.

**Discontinuation of smoking.** Why do smokers not give up the habit that so many state they would like to shed? Despite pronouncements from health authorities in all parts of the world, the proportion of smokers reporting successful discontinuation of smoking is from 10 to 20 per cent in males and 3 to 10 per cent in females (Haenszel et al. 1956, p. 24; Hammond & Percy 1958, p. 2,956; Cartwright et al. 1959, p. 726; and Horn 1963, p. 391).

Immediately following the 1964 report of the surgeon general of the United States, 8.6 per cent of the smoking students at two U.S. colleges reported that they stopped smoking as a result of the health hazard identified in this report (Katahn et al. 1964). Again, a greater percentage of male smokers (10.3 per cent) than female smokers (5.9 per cent) reported quitting. In addition, more natural science majors (18.2 per cent) quit smoking than did liberal arts majors (6.7 per cent). The same students took a story-completion test requiring them to create both an imaginary story and an estimate of the amount of time which in reality would have transpired during the occurrence of the sequence of events in the story. Ex-smokers tended to respond with a longer time perspective than did students who continued to smoke, and the authors suggest that these individuals might be more likely to worry about long-term health hazards.

Immediately before and following the surgeon general's report, several researchers attempted to find effective means for discouraging initiation and encouraging cessation of the smoking habit. Horn (1960) used a variety of educational approaches with high school students in Portland, Oregon, but he reported only minimal success in preventing the initiation of smoking. Both Horn (1964, personal communication) and Lawton (1964, personal communication) have attempted to help adult smokers discontinue smoking through the use of weekly educational meetings (Horn in Washington) and weekly "group therapy" sessions (Lawton in Philadelphia). With both techniques, success rates were not much higher than the 10 to 20 per cent "spontaneous" successes reported by other writers. The Horn and Lawton studies raise an important question for all cessation studies: who is an ex-smoker? Is he an individual who quits for a week, a month, a year, or forever? It is both a common observation and an established statistical fact that

many ex-smokers resume the habit after varying lengths of time.

**Comment.** After reviewing the above literature, the present authors have concluded that, in all probability, people begin to smoke for essentially the same reasons that they adopt other habits, such as eating certain foods, using certain brands of soap, wearing lipstick, going to see the Beatles, and so forth. That is, initiation of smoking appears to be a result of the millions of dollars spent yearly by (cigarette) manufacturers to influence people to do so; the standards and fads extant in youthful and adult social circles; the examples provided by parents and families; the depth of commitment to personal religious codes; and, finally, some psychological and personality characteristics (e.g., extraversion, tension, neuroticism, etc.) of the individual himself. In our opinion, the last category (personality characteristics) is the least influential in determining whether a given individual will begin to smoke, whereas the other factors (especially the amount spent on world-wide advertising) have considerable influence. Once started, however, continuation or discontinuation appears to be, in large part, a function of the sociopsychological characteristics of the individual.

### SNOUCK HURGRONJE, CHRISTIAAN

Christiaan Snouck Hurgronje (1857-1936), Dutch orientalist and colonial official, was educated at Leiden University. He was a lecturer at his alma mater between 1880 and 1889 and for 17 years thereafter was an adviser on religious and native affairs to the Netherlands Indies government. From 1906 until his death, he was professor of Arabic and Islamic institutions at Leiden and concurrently (until 1933) adviser to the Ministry of Colonies.

Snouck Hurgronje is best known as one of Europe's two nineteenth-century pioneers in the scientific study of Islam (the other being the Hungarian Ignaz Goldziher). His rigorously critical, historical approach, based on close scrutiny of scriptural texts and Arabic commentaries, shed new light on such crucial problems as the origins of the faith and the role of Muhammad in its growth and development, and the nature of the *hadith* (the recorded usages and traditions of the Prophet and the early Muslim communities). Snouck was the first to recognize the central role in Islam of the *fiqh*, i.e., a repository of quasi-judicial regulations pertaining not only to legal and social affairs but also to the relation of the individual to Allah, and of the *idjma*, i.e., the "consensus" on interpretations of the *fiqh* reached by the four recognized schools of Islam, which is binding on all Muslims. At the same time Snouck Hurgronje critically re-examined Islam as a historical reality, reconstructing, on the basis of the Qu'ran (Koran) and the *hadith*, the origins of the first Muslim communities, with special emphasis on the adaptations to pre-existing rituals instituted by Muhammad. Snouck was also the first to clarify

the interplay between pre-Islamic usages ('*āda*) and *fiqh* and hence the pattern of diversity within unity. Islamic eschatology, especially that centering on the Mahdi, and Islamic mysticism were other important fields opened up by him, which were subsequently thoroughly explored in the Indonesian setting by some of his outstanding Dutch students.

Although Snouck was recognized as a leading authority on Islam in European and Muslim lands even during his lifetime, his other achievements have as yet received only scanty scholarly attention. Apparently without formal academic training in anthropology, Snouck produced ethnological and ethnographic studies of lasting importance. It was his concern for Islam as a living reality, his sharp sense of observation and his mastery of both scriptural and vernacular languages, and his careful field work that permitted him to do so. His classic two-volume work, *Mekka* (1888–1889), the result of his sojourn there in 1885, typically combined a reconstruction from original texts of the Holy City's history with vivid, detailed descriptions of daily life, gathered in "coffee shops, *ditwans*, mosques and living quarters." Snouck almost intuitively grasped the concept of "culture," as is evidenced in the preface to his standard work on the Achinese of northern Sumatra (1893–1894): "To him who really wants to penetrate the Muhammadan factor in the life of a people, children's games, adult entertainments, profane literature, the organization of a village or province—all these are in many respects as important as are the books used in religious instruction, the mystical orders propagating in the land, the position of the scribes" (1893–1894, vol. 1, p. xii). A similar perceptiveness pervades his observations on Javanese Islam, published (in part only) pseudonymously in 1891–1892 as a series of letters from a retired Javanese district head.

As lecturer in a training institute for colonial officials from 1880 on and as the first Dutchman to gain on-the-spot knowledge of the Indonesian ("Djawa") colony in Mecca, Snouck Hurgronje was throughout his career deeply and often passionately involved in the problems confronting a European colonial power ruling millions of Indonesian Muslims. His studies on the Achinese and Javanese were written while he served the colonial government in an advisory capacity; the insights he gained during his Achinese mission were instrumental in terminating a desultory, decades-old and Muslim-inspired war against the Dutch. But more than a mere adviser, Snouck was in fact the

originator and architect of modern Dutch Islamic policy, a policy basically adhered to until the end of Dutch rule in Indonesia in 1942. Its twin principles were the broadest toleration of religious life, on the one hand, and rigorous repression of Islamic, especially pan-Islamic, political agitation, on the other. Although the dividing line was as difficult to determine in theory as in practice, particularly after the advent of Islamic reformism in Indonesia (after Snouck had returned to Holland), the twentieth-century Islamic renaissance in the archipelago was doubtless facilitated by the colonial government's adherence to Snouck's directives.

However, there is a tragic paradox in the fact that, in spite of his lasting influence on Islamic policies, Snouck Hurgronje was least successful as a colonial statesman in the wider sense of the word. He was one of the very few Dutchmen with a bold vision of the ultimate destiny of peoples under colonial domination and virtually the lone propounder of the associationist ideal that envisaged a future political union between Holland and Indonesia as equal partners sharing a common cultural bond. He was a fervent proponent of rapid Westernization through education, which he believed would readily supplant indigenous, including Muslim, orientations, especially among the Javanese aristocracy. Snouck argued in favor of progressive Indonesianization of the administration, which was to go hand-in-hand with a planned withdrawal of European supervisory personnel. Especially in the years after World War I, he became one of the most resolute Dutch advocates of ultimate Indonesian independence.

Dutch colonial practice in the twentieth century, however, took a course which was diametrically opposite to that which Snouck Hurgronje advocated. His departure from Indonesia in 1906 had been caused by his inability to persuade the colonial authorities to supplement pacification (in Achin) with meaningful social reconstruction. The iron logic, merciless irony, and uncompromising vehemence with which he argued his case (his later, presumably highly critical, advisory opinions to the Ministry of Colonies have not yet been published) made him the idol of many liberals but also the *bête noire* of diehard colonial conservatives. In order to undercut his influence and that of his colleague Cornelis van Vollenhoven in the training of colonial administrators at Leiden University, these conservatives in 1925 established a rival department of Indonesian studies at the University of Utrecht.

Snouck's failure as a colonial administrator should not obscure his lasting stature in the field of Islamic studies. Social scientists have not yet fully come to appreciate his contributions to many of their specialties.

| III. THE REGULATION OF ANIMAL POPULATIONS | V. C. Wynne-Edwards |

### I THE FIELD

Social behavior may be defined as any behavior which is stimulated by or has an effect upon another animal of the same species. So defined, almost all behavior may have some degree of sociality—and it is therefore proper to speak of behavior as highly social or only minimally so—but there is very little behavior which can be called truly asocial. Social behavior is therefore very nearly equivalent to behavior in general, as the same behavior may be social or not, depending upon its source of stimulation and its object. To qualify the above definition further, there are occasions, particularly in cases of domestication or hybridization, in which social behavior can be elicited by a member of another species.

**Behavior patterns.** A behavior pattern may be defined as a segment of behavior having a definite adaptive function, and therefore, as a basic functional unit of behavior. For example, a chicken approaching a pan of water, lowering its bill into the water, and then raising its head is exhibiting a pattern of behavior which has the function of providing the animal with water.

**Distribution of social behavior.** The paramoecium, so commonly studied in elementary biology courses, is a highly developed protozoan which exhibits a variety of behavior patterns. One of these is a simple form of sexual behavior in which the paramoecia fasten themselves together and afterward exchange nuclei and divide. Another pattern occurs under unfavorable environmental conditions. When a drop of water containing several paramoecia is allowed to dry slowly, the animals will huddle together and thus protect each

other against drying out. Such behavior has the function of shelter or comfort seeking. In addition, this one-celled animal shows other patterns of behavior which are only incidentally social. One of these is an investigatory or exploratory pattern of behavior in which the animal drives itself ahead with its cilia in a spiral path and thus comes in contact with various objects. Depending on the nature of the objects, it may remain in contact or back off and start out in another direction. Finally, its pattern of ingestive behavior is extremely simple, consisting of driving water laden with food particles toward its gullet by means of cilia, and it involves only starting or stopping the beating cilia.

More complex patterns of behavior having basically the same functions are present in the lower invertebrates, but only in the arthropods and vertebrates can we find new functions. Male crayfish, for example, will fight with each other during the breeding season, an example of *agonistic* behavior. Certain insects show highly developed patterns of behavior for the care of the young, thus exhibiting care-giving, or *epimeletic*, behavior. The young larvae, by their movements, may signal for care and attention, exhibiting care-soliciting, or *et-epimeletic*, behavior. Likewise, ingestive behavior assumes a highly social function, especially among ants, which feed each other in a relationship that Wheeler (1923) called *trophallaxis*.

All of these behavioral functions are highly developed in vertebrates. In addition, superior eyesight permits vertebrates to develop patterns of social behavior which involve mutual imitation; this *allelomimetic* behavior is commonly seen in schools of fish, flocks of birds, and herds of mammals, where each animal follows the movements of those next to him, resulting in highly coordinated group movements (Scott 1958).

**Systems of behavior.** As behavior becomes more complex in the animal kingdom, a given species develops several alternate patterns of behavior for each general function. A paramecium, for example, has only one simple pattern of ingestive behavior and no patterns of agonistic behavior. In contrast, a mouse attacked by another mouse may fight back, run away, assume a defensive posture, or become limp and passive. Each of these patterns of behavior has the function of adapting to the same stimulus, and the attacked mouse usually goes through all or part of this behavior repertory until one response is finally selected on the basis of its effect. Such a group of behavior patterns having a common general function, and usually a common physiological basis, is a *behavioral sys-*

*tem*. Behavioral systems are quite similar to physiological systems, and many of them are directly related, as for example, sexual behavior and the reproductive system. Like physiological systems, behavioral systems do not function entirely independently of each other, and in various species they may be organized on a somewhat different basis. In the dog and other members of the family Canidae, sexual and eliminative behavior are closely related to each other, whereas in birds the two are unrelated.

The nature of behavior patterns and their organization into a system is largely a result of the special heredity of the species concerned. A primary task in studying the social behavior of any species is to describe its special behavior patterns and their organization into behavioral systems. This behavioral inventory, or ethogram, as Tinbergen has named it (1951), provides the essential raw material for understanding social organization or conducting experimental work.

**Development of behavioral systems.** In most of the higher animals, behavioral systems are incompletely developed at birth or hatching. In young mammals the ingestive system is present in an immature form, the newborn animal taking its food only by nursing. The development of behavior patterns for ingesting solid food comes later. Some systems of behavior may be completely absent, and all of them tend to be loosely organized together as *et-epimeletic* behavior. As the animal grows older, both behavior patterns and behavioral systems become differentiated from each other, partly as the result of learning and partly because of the processes of growth and maturation.

### Social organization

**Social relationships.** A social relationship may be defined as regular and predictable behavior between two individuals, usually of the same species. In some animals these relationships may be organized largely as the result of heredity, but in higher animals relationships develop as a combined result of hereditary factors and learning. When two chickens meet for the first time, each presents a problem of adaptation to the other, and one solution is to attack. The result is a fight, and usually one chicken wins and the other loses. When they meet again, there is a tendency to repeat the behavior, so that in the long run one individual forms a strong habit of winning and the other of losing. Since one of the principles of learning is the "law of effect" (which might also be called the law of least effort), the winning chicken reduces its attacks as time goes on, and the whole

relationship is reduced to one of threat and avoidance behavior rather than actual fighting. This is an example of a typical dominance-subordination relationship. [See LEARNING, *articles on INSTRUMENTAL LEARNING and REINFORCEMENT.*]

Hereditary factors also help to determine the development of the relationship. If one bird is a male and the other a female, the male almost invariably wins. Among females, large hens are likely to win over small ones, and aggressive breeds over peaceful ones (Guhl 1953).

Thus, the development of a social relationship may be considered as a process of differentiation of behavior, affected by both heredity and learning. As will be seen below, the development of social relationships in young animals is a slower and more complex process.

Social relationships can be classified in two different ways. In Carpenter's system, classification is based on the different kinds of individuals present in the system (1934). In howling monkeys and most other mammals there are three major kinds of individuals (males, females, and young) combined in six kinds of social relationships (see Table 1). The same scheme applies to all social vertebrates, but it becomes more complex in some of the social invertebrates. In bees there are three kinds of adults—males (drones), females (queens), and sterile females (workers)—as well as the young. In addition, the workers exhibit different behavior at different stages of development. In termites there may be as many as three different kinds of individuals capable of reproduction and as many more different kinds of workers.

Table 1 — Social relationships classified according to age and sex

	Male	Female	Young
Male	Male-male		
Female	Male-female	Female-female	
Young	Male-young	Female-young	Young-young

Source: After Carpenter 1934.

Social relationships may also be classified according to the behavioral system or systems involved. On this basis a large number of social relationships are theoretically possible, but actually observed, important social relationships are relatively few in number. There are four which involve one behavior system only. *Dominance-subordination* relationships are developed in any animal system where agonistic behavior is found. *Sexual* relationships depend of course on sex behavior. *Leader-follower* relationships are based on allelomimetic behavior and result from an unequal

degree of mutual imitation. Finally, *mutual-care* relationships, often seen in the mutual grooming of primates, are formed when both animals exhibit epimeletic behavior.

There are two important relationships composed of combined systems: trophallaxis and care-dependency. Trophallaxis involves mutual feeding and mutual care and is very important in the social insects. The workers feed the young and in turn lick off secretions from them. In mammals, birds, and other vertebrates which care for their young, epimeletic and et-epimeletic behavior are combined to produce the relationship of care-dependency.

Both of these schemes of classification may be combined for systematic study. For example, the behavior exhibited in a male-male relationship may be examined in detail and classified as dominance-subordination, leader-follower, or whatever it may be in the particular animal society.

The number of possible social relationships which an animal develops depends on the size of the group. Carpenter has presented a simple formula for the total number:  $n(n-1)/2$ , which is of course the number of possible combinations between any two individuals in a group of  $n$  individuals. When examined in more detail, this formula has certain interesting properties which have implications for the social organization of groups. If we consider groups of different sizes, starting with one and going up to ten, we see that an individual added to a group adds a number of relationships equal to the number of individuals already present, i.e., an individual joining a group of three adds only three new relationships, but adds ten to a group of ten. There is a very rapid increase in the number of relationships as the group gets larger, resulting in extremely complex organization. Experiments indicate that hens in a flock of one hundred can recognize every other individual, making a theoretical total of 4,950 relationships in the flock. Social activity tends to increase in proportion to the number of social relationships.

**Primary socialization.** In highly developed societies the individuals must become related to particular members of the species. An ant colony would become totally disorganized if its members reacted toward members of other colonies in the same way as to their own. Ants would wander from one nest to another, overcrowding one and leaving young unprotected in others. Therefore, at some period in their development, all individuals must learn to differentiate their own family or colony from others. As Fielde (1903) showed,

there is a critical period in early development in which the immature ant can be transferred from one nest to another or even to that of another species and subsequently act as if it belonged with the new individuals. This transference of social relationships occurs regularly in the slave-raiding ants, a species of red ant commonly found in North America. The raiders remove the pupae from nests of black ants and take them to their own, where the black individuals subsequently rear and care for the offspring of the raiders.

A similar phenomenon takes place in all highly social animals which have been studied so far. Birds hatched in incubators or removed from their nests in early stages of development and reared by hand become attached to the human species and often fail to react to their own. In precocial birds, such as chickens, ducks, geese, and turkeys, the formation of the first social relationship takes place within the first 24 hours after birth. In the more slowly developing altricial birds, such as song sparrows, jackdaws, or doves, the process takes place at a later period in development, and the degree of attachment to the human handler varies inversely with the age at which the young are taken from the nest [see IMPRINTING].

Among mammals, also, the process varies with speed of development. In sheep and other herd animals the young lamb becomes strongly attached to its mother within the first few days, whereas in the more slowly developing dog the period of socialization begins at about three weeks of age, reaches a peak at about six or seven weeks, and slowly declines thereafter. The process of socialization is of course a reciprocal one, the parents becoming attached to their offspring as well. In sheep or goats the mother becomes attached to her offspring within the first two hours or so and thereafter will repulse any strange infant. Primary socialization has been little studied in primates other than man, but it takes place within the first six months in rhesus monkeys, as also appears to be the case in human infants [see INFANCY, article on THE EFFECTS OF EARLY EXPERIENCE].

The time at which primary socialization takes place is obviously a critical period in development, determining which individuals shall be the close relatives of the young animal. Later he may exhibit appropriate patterns of sexual behavior and other types of social interaction toward similar individuals [see AFFECTION; SOCIALIZATION, article on PSYCHOLOGICAL ASPECTS].

What is the nature of the process involved in primary socialization? In the young animal there are positive behavioral mechanisms such as the

"following" reaction of a young chick or lamb, which brings it into contact with members of its own species. There are also negative mechanisms, particularly the behavior patterns of escape, which develop somewhat later and prevent socialization with other individuals by inhibiting contact. As to the nature of the process itself, in precocial birds it obviously takes place in the absence of food rewards, and, under experimental conditions, without any obvious external rewards or reinforcement of any kind. While food rewards do affect the behavior of a young mammal, experiments have shown that the process of socialization takes place without them. All evidence indicates that the process is an internal one and is closely connected with emotional responses. Experimental studies indicate that any kind of strong emotion, whether it be that of loneliness, fear, pain, or hunger, will speed up the process of forming a social bond. While the capacity to form such a bond is strongly developed in the infant animal, the same process can take place at any time in later life at a somewhat slower rate, except when it is completely suppressed by the development of interfering behavior patterns (Scott 1962).

### Animal and human societies

The kind of social organization developed by a species depends upon the nature of its behavior patterns and the ways in which they are organized into behavioral systems. Thus we may state a general law: Social behavior is a determinant of social organization.

**Aggregations.** The simplest kind of animal society is the temporary aggregation. Such groups occur widely in the animal kingdom and were extensively studied by W. C. Allee, who was able to show in a large number of cases that living in groups promotes the survival of individuals, whether they are protozoans or vertebrates (Allee et al. 1949). This kind of temporary aggregation is based on shelter- or comfort-seeking behavior.

A second kind of temporary aggregation is based on sexual behavior. This may involve only two individuals, as it does in paramecia, or vast numbers, as in the mating swarms of the palolo worm of the Pacific. The great majority of invertebrate societies belong to one or the other of these temporary aggregations.

In contrast, the higher invertebrates, and many vertebrates, form long-lasting groups with highly complex internal organization. Insect groups first received scientific attention, but it is now realized that the social behavior of insects is somewhat specialized, being limited by certain anatomical

peculiarities such as the external skeleton and the relatively inefficient compound eyes. Because of these limitations, insects are small, relatively short-lived, and unable to respond to complex visual stimuli at a distance.

**Insect societies.** The most highly developed insect societies belong to two orders, the Hymenoptera, including ants, bees, and wasps, and the Isoptera, or termites. In both orders the societies consist of permanent groups associated with nests that are constructed by the combined efforts of the members, and the most prominent social behavior is care giving. In an ant colony two workers meet, feel each other with their antennae, and if one has recently fed, it will regurgitate a drop of honeydew to be eaten by the other. This, together with care of young, constitutes most of their social behavior and is what Wheeler termed trophallaxis (1923).

In any given species of insect, social organization tends to be rigid and stereotyped, repeating itself generation after generation. There is relatively little modification by experience, and the combined efforts of the individuals produce a stable social environment. Alfred Emerson points out that insect societies have many of the characteristics of a single organism, and he has called them "supra-organisms" (see in Allee et al. 1949).

The peak of development of the insect society is reached by the common honeybee, which maintains a permanent social group. In contrast to ants, in which each new colony is formed by a mated pair, large numbers of old bees accompany a queen moving to a new hive. Mating takes place at this time, and the fertile female, or queen, continues to reproduce for a long period, sometimes two or three years. The vast majority of the colony members are short-lived sterile females or workers which go through a regular series of activities as they pass through a few weeks of active life, first working around the hive and finally going out to forage for food. As von Frisch discovered, foraging bees are able to communicate to other workers the direction and distance at which food is found by means of body movements, or "dances," when they return to the hive (1950). Present evidence indicates that the nature of the signals and the ability to understand them are determined by heredity rather than learning.

**Vertebrate societies.** The societies of vertebrate animals are also related to basic anatomy and physical capacities. Vertebrates have an internal skeleton and hence are capable of continuous growth. They can become immensely large, and their life spans may be enormously extended in

comparison with insects. The capacity for learning is consequently much more valuable and plays a more important role than it does among invertebrate societies, so that there are many examples of cultural as well as biological inheritance. Furthermore, the vertebrate eye is vastly more efficient than the compound eye of arthropods, making mutual imitation or allelomimetic behavior possible, particularly for animals active in the daytime.

There is an enormous variety among vertebrate societies, ranging from temporary aggregations, like those of the lower invertebrates, to societies far exceeding those of the insects in complexity. The most highly developed societies are found among animals which occupy dominant ecological positions.

In the water, fish are still the dominant form of life, and their societies have taken two forms. One of these, the school, which is based on allelomimetic behavior, is very widely found. In herring or mackerel the fish move in groups throughout their lives, even spawning in a mass and paying no attention to the eggs or young. In contrast, there are many kinds of fish, like the sunfish and stickleback, which emphasize nest building and the care of the young. In these cases the male guards the nest and sometimes the young for a short period after hatching. The period of dependency remains short, however, as in most cases the young must feed themselves. The males guard definite boundaries around the nest and thus exhibit territoriality (Tinbergen 1953).

Amphibians, which usually occupy a relatively inferior ecological niche and are under constant pressure for survival, show almost no social organization except temporary mating aggregations and a few examples of care of the young. The same can be said for many reptiles, although some lizards develop dominance and territoriality and alligators build nests and briefly protect their young.

Birds, which are the dominant form of life in the air, show a great variety of highly developed societies. One of the characteristics of bird societies is the phenomenon of seasonal change. For example, during their brief mating season, song sparrows develop one sort of social organization involving sexual behavior, territoriality, and care of the young and then spend the rest of the year in flocks which are much like schools of fish. Since the young are produced as eggs which have to be incubated, a high degree of coordination of care-giving behavior and physiological processes is necessary, and in many birds this is exhibited by both

sexes, which combine to build the nest and care for the young. Many species feed their young, and pigeons and other members of the dove family nourish their offspring with crop milk. A "nuclear family" of male, female, and young is characteristic of these and many other bird societies, but in chickens and other members of the same family, mating is polygamous, and the brood of young is raised by the female alone.

In mammals there is an enormous variety of societies differing in structure and degree of complexity. Among rodents, woodchucks are relatively solitary animals, reacting to each other with agonistic behavior except during the brief mating and reproductive seasons (Bronson 1964). At the opposite extreme are the prairie dogs, which run to groups numbering thousands of individuals. Each prairie dog colony is subdivided into territories, usually occupied by a sexually mature male, a group of females, and their young. Each year the adults in the territory move out to new locations on the edge of the colony, leaving the burrows behind for the next generation. Thus the oldest and most experienced members of the colony are found on its edges, where adaptation is more difficult (King 1955).

Other examples of mammalian societies are the great herds of hoofed mammals. In a typical society, such as that of mountain sheep, the two sexes mingle during the mating season. Males compete in individual combat, and the more successful ones do most of the mating. During the rest of the year there are separate male and female herds, the latter being the group in which the young are raised. Among these herds a definite leadership organization develops, the older animals of either sex tending to lead in their respective groups.

Some carnivores are quite solitary in their habits, but others, like wolves and dogs among the Canidae and lions in the cat family, live in permanent groups. These are, however, much smaller than those of the herd animals on which they prey.

Thus, we see that there is an enormous number of different kinds of animal societies. There is great variation among human societies, but the variety possible in other animals far exceeds it. It is therefore of considerable interest to see what kinds of social organization are present in man's closest biological relatives, the other members of the Primate order.

**Primate societies.** Like other important orders of mammals, the primate group includes a wide variety of species, ranging from the small "bush

babies," or galagos, of Africa to the large manlike apes and man himself. Primates can be at least as different from one another as cats are from bears in the order Carnivora. Their chief limitation of variation is an ecological one. Except for man, they live entirely in tropical and subtropical regions, and while many primates like to play with water, none of them is truly aquatic.

That primates other than man are highly social was first established by Carpenter's classical study of the howling monkey (1934). These are tree-dwelling primates of Central America. A band of males, females, and young wanders from tree to tree, eating fruits and leaves and rarely descending to the ground. Their most obvious kind of social behavior is allelomimetic, since they are constantly following each other. The more active males generally take the lead, but there is no single established leader in their wanderings. Agonistic behavior is greatly reduced and expressed almost entirely as the vocalization that gives the species its name. Females in estrus pass from male to male, and there is no indication of sexual jealousy or rivalry over females. The most important social relationship within the group is that between mother and offspring, the mother constantly carrying and caring for her baby for the first two years of its life. Care-giving behavior is also shown by the males if a young animal falls to the ground or is threatened in some way. Different bands have roughly marked territories, and groups keep each other apart by means of threats.

Like man, baboons are a plains-living primate, and for this reason their social life has particular interest. Biologically they have evolved toward a doglike structure, often running on all fours and developing enormous teeth. However, they are largely vegetarian rather than hunting animals, often eating grass which they pick and eat a blade at a time. They readily adapt to living off farm crops, particularly melons and vegetables, and can be enormously destructive (Washburn & DeVore 1961; DeVore 1965).

As with howlers, a large part of their social behavior is allelomimetic, and they move in a group of males, females, and young which may include thirty to one hundred individuals. Agonistic behavior is more prominent than in howlers, and the males develop a definite dominance order. As the group moves, the most dominant male stays in the center, while the more subordinate animals keep their distance from him and each other. Living on the plains, the group is constantly threatened by large predators such as lions and cheetahs. Females and their young tend to group themselves toward

the center of the group, near the dominant male, this being the safest spot. When a member of the group is attacked or threatened, all the males combine in its defense. Consequently, baboons are seldom actually harmed by predators. When in estrus, a female may mate with the most dominant male first but then move on to others as he becomes satiated. As with howlers, there is no evidence of sexual jealousy or permanent bonds between particular males and females. The most important social relationship is that between mother and offspring; in fact, all adults are extremely responsive to young animals and will approach and care for them if the mother permits. As the infant becomes more independent, it joins a play group of other young animals within the group. In general, the baboon society gives the impression of a closely knit and highly cooperative group.

Macaques are related to baboons, and their behavior is somewhat similar. The Indian macaque, or rhesus monkey, commonly lives near human habitations and is often fed by people. Carpenter studied an artificial colony of rhesus monkeys on Santiago Island off Puerto Rico and demonstrated that a dominance order between the males was an important part of their social life (1942). As with baboons, females in estrus pass from male to male. Overt aggressive behavior is perhaps more common than in baboons, possibly because of the disorganizing effect of human contact. Southwick found that where rhesus troops went into cities and competed for food, there were many cases of serious injury (1963).

The behavior of the Japanese macaque is quite similar. Imanishi reports that the animals spend their lives within a troop composed of males, females, and young (1960). The most dominant male usually occupies the central position, surrounded by females, while the younger and less dominant males keep to the outside of the troop and also precede it when it is moving. As with baboons, there is no subdivision of the troop into families or any permanent consortship between individual males and females.

The Indian langur, or Hanuman monkey, is a tree-living species and exhibits much less aggressive behavior than the macaques. However, Jay has described a definite dominance order among males (1965a; 1965b). All females are subordinate to all males, except when an infant is threatened, and their own dominance order is not a clearly marked one. Sexual behavior is relatively unimportant, as the females have only a five-day estrus period per month and this is absent during pregnancy and lactation. Females have some tendency to consort

with the most dominant male, but there is no absolute correlation, and in one group studied by Jay the most favored male was a low-ranking one. Male-female consortships never last more than a few hours. In contrast to baboons, males pay little attention to the young, but infants, and particularly the newborn ones, are the object of much attention from all females in the troop. Males tend to take the lead when the group moves.

The manlike apes have been very difficult to study in the wild. In his original study Nissen (1931) was able to see very little besides the retreating chimpanzees disappearing into the tops of the tropical forest. More recently, Kortlandt located a favorable area on a Congo plantation where chimpanzees were protected and were in the habit of coming into the open (1962). Reynolds and Reynolds were able to keep track of a group of chimpanzees in the Budongo forest of Uganda with the aid of a large group of spotters scattered through the dense vegetation (1965). Unlike baboons, chimpanzees do not live in compact groups, but forty to fifty individuals may occupy an area of six to eight square miles. Except for females and their offspring, there are no permanent associations between individuals, and temporary groups of males and females, females and young, males, and groups containing all kinds of individuals are found in approximately equal numbers. Agonistic behavior is uncommon, and there are few indications of dominance and subordination. During estrus the same female may mate with several males in succession, and no fighting is observed between them. Chimpanzees appear to keep in touch with each other by vocalization, and on many occasions groups will join in vocalization over a large area. There is little evidence of leadership under most conditions and no reports of defense of territorial boundaries. Thus, chimpanzees form a very loosely knit but mutually tolerant society, with loose temporary associations between individuals, except for the mother-offspring relationship.

Goodall has studied chimpanzees in the comparatively open forests of the Gombe Stream Reserve in Tanganyika and has been able to follow the behavior of identifiable individuals over a period of several years (1965). Her more detailed accounts of behavior confirm the general picture of chimpanzee social organization. In addition, she has observed occasional predatory behavior and meat eating. These chimpanzees also exhibit use of tools, in particular, poking twigs or rolled-up leaves down the holes of termites in order to collect them for food.

The behavior of gorillas under natural conditions is also surprising. With their immense size these animals have little to fear from predators and within their own social groups are placid and peaceable. They are strict vegetarians, and the two sexes are so much alike that they are almost impossible to distinguish at any distance. Their sex organs are very small, and sex behavior plays a very minor part in their social life. Unlike chimpanzees, gorillas live in small compact groups containing both sexes and all ages of individuals. According to Schaller, there is a strong system of leadership, all members of the group responding to one of the older males (1963). Dominance is expressed almost entirely in the form of allowing precedence, and it is strongly related to age.

The only one of the manlike apes that shows anything like the human nuclear family of male, female, and their offspring is the gibbon. These long-armed tree-dwelling animals of southeast Asia are highly aggressive in both sexes, and the largest social group is a male, a female, and their immature offspring. Other groups are kept away by threats and fighting. Rather than supposing this to be the beginning of evolution toward a nuclear family, we can advance the hypothesis that the gibbon group is formed by a reduction of the troop to the smallest unit which is still biologically functional.

Primate societies do not present an evolutionary history of human social organization. Rather, each species has evolved its own social organization, producing an astonishing variety against which it is possible to compare and contrast human social organization. The one thing which is constant in all primate societies so far studied is the emphasis on the care of the young, particularly by the mother but also by unrelated males and females in the highly social forms. Agonistic behavior varies a great deal, as does sexual behavior. Most primates show regular periods of estrus, although there is some indication of a tendency toward a more extended receptivity in female chimpanzees. Was the social organization of our primitive human ancestors more like troops of rhesus and baboons, or was there a tendency to form temporary separate groups based on sex and age, as in the chimpanzee? The almost universal tendency toward division of labor in human societies suggests the latter. The animal data also suggest that the human nuclear family is perhaps not the beginning but the end point of human social organization, resulting from situations which demand great fluidity; that is, the nuclear family represents the ultimate reduction of family organization to the simplest

unit which is still capable of all the functions of biological reproduction [see FAMILY].

**The evolution of social organization.** Social organization is based on behavior, and behavior leaves no fossils. Therefore, any reconstruction of the evolution of animal societies must always be hypothetical and based on what we know about living animals. Assuming that the more lowly organized forms of living animals are similar to those which existed millions of years ago, we can suppose that there are two general bases for the initiation of social life. One of these is shelter-seeking behavior, in which animals stay together because the bodies of their fellows form a favorable environment. If this sort of behavior is extended, it should result in the animals' following each other around, i.e., *allelomimetic* behavior. Animals that do the latter must have both motor equipment for rapid coordination and the necessary sense organs to keep in touch with each other. This kind of social group approaches its highest development in schools of fish, flocks of birds, and herds of mammals.

The other kind of social behavior which we may assume to be primitive is sexual behavior, which results in more efficient means of reproduction than scattering the sex cells broadcast. Retaining the eggs after they are fertilized and giving them care after they are laid still further increases the efficiency of reproduction, and the height of this kind of behavior is seen in two widely different parts of the animal kingdom—societies of insects and those of many birds and mammals.

These two basic kinds of social organization may evolve independently of each other, or both may occur together in the same species. In many cases social organization is quite independent of physical form, and closely related species may be either highly social or relatively unsocial. For example, the deer family range from the highly social elk through the more solitary Virginia deer to the moose, which is almost completely solitary except during the brief mating season and the association of a calf with its mother. Among rodents there is the prairie dog, a ground squirrel that lives in colonies of thousands of individuals, and at the opposite extreme, woodchucks, which lead highly solitary lives except for the brief necessities of mating and rearing the young. Even in the social insects there are close relatives of honeybees which build solitary nests. Thus there is no consistent relationship between biological form and social behavior, and the evolution of societies has become largely, though not entirely, independent of the anatomy of the individual. Consequently, in search-

ing for the origin of human sociality, it is not possible to find anywhere the recapitulation of human social prehistory. The study of animal societies can at most suggest ideas and provide a basis of comparison.

**The problem of basic human nature.** In addition to biological evolution, human societies have added a new dimension: cultural evolution. The beginnings of this can be seen among the higher animals where the offspring learn fears from the previous generation. However, human language has enormously increased the potentiality of passing information along from one generation to another, and written language permits its accumulation over almost infinite times and in enormous amounts.

Compared to biological evolution, the study of cultural evolution is still in its infancy. Very little progress was made in the theory of biological evolution until the mechanism of heredity was discovered. Reasoning by analogy, we may suggest that the development of an adequate theory of cultural evolution will in part depend on our knowledge of the mechanism of cultural heredity, namely learning, and its application to cultural phenomena.

Unlike biological evolution, which moves in terms of generations, cultural change can occur with extreme rapidity and can be measured in terms of years. This raises the possibility that cultural change may move so fast that it exceeds the biological capacities of man in respect to social behavior. [See CULTURE, article on CULTURE CHANGE.]

Here again we are handicapped in our scientific information. There is no way of restoring precultural man to life and discovering what sort of social existence he led. Judging from existing animal societies, however, we may assume that his social behavior was well adapted to a particular kind of stable social organization. Beyond this, all we can do is to observe present-day human beings and study their social behavior under varying conditions. We know that sexual behavior plays an important role. Instead of definitely limited periods of sexual behavior, human females have very nearly reached the situation of constant receptivity, if not constant estrus, and there is no seasonal limitation on either sex. We know also that, because of the relatively slow developmental rate of human infants, care-giving behavior is highly important, as is the care-soliciting behavior of the young. It is likewise obvious that care-giving behavior is often extended to adults as well as to children and that it exists in both sexes. Young children are there-

fore one of the focal points of human societies, and as with all primate societies, the relationship between old and young is an important one. As with any highly social species, we may assume that human beings have evolved behavioral capacities for the control of agonistic behavior, partly through forming habits of not fighting while young and partly through the formation of dominance-subordination relationships. These facts are almost self-evident. It is not as well recognized that human beings are also highly allelomimetic, with strong tendencies to do what others around them are doing. Because of differences in age and sex, allelomimetic behavior may be difficult in mixed groups, and we can observe a tendency for human groups to sort themselves out on the basis of age and sex. [See AGGRESSION; IMITATION; LEADERSHIP.]

Besides these major types of advanced social behavior, human beings continue to show all of the more primitive sorts of social behavior, for example, ingestive, eliminative, shelter-seeking, and investigative. In regard to the last, another characteristic of human beings is that they are highly curious. We can conclude that human beings show all of the basic kinds of social behavior in strongly developed form, and we can advance the hypothesis that any successful form of cultural organization of society must provide for reasonably satisfactory development and expression of these types of behavior. Conversely, any form of organization which attempts to completely suppress or distort a fundamental kind of behavior will result either in the dissolution of the society or maladaptive behavior on the part of the individual within it.

Man is a large, bipedal, diurnal primate closely related to the living great apes. Human behavior is based on a rich social heritage made possible by a tool-dependent culture and the unique properties of language. However, in most of the fundamental features of his social life, such as prolonged care of immature offspring and lifelong association between related adults, man is a typical Old World primate. Because man is most closely related to the Old World monkeys and apes, the following discussion is confined primarily to these forms and directed to those issues of most interest to the social sciences.

**Living primates.** There are about six hundred varieties of living nonhuman primates, divided into some fifty genera and two hundred species. Because of this extraordinary diversity, ranging from such forms as the small, insectivorelike tree shrews and "mouse lemurs" to the great apes and man, it is sometimes assumed that the behavior of living primates can be arranged along an evolutionary scale of increasing behavioral similarity to man. However, no living primate is the ancestor of any other, and many varieties have had separate evolutionary histories for tens of millions of years. Every living species has survived by specialized adaptations, and while it is possible to make some broad generalizations about the physical characteristics of prosimians, monkeys, and apes (Clark 1960), behavioral comparisons are more difficult. Washburn and Hamburg (1965) have recently discussed the classification of the primate order from a behavioral point of view.

The many varieties of monkeys alone range in size from creatures weighing less than a pound to others weighing more than one hundred pounds. They have exploited a wide variety of jungle and open woodland habitats, frequently achieving population densities of one hundred or more individuals per square mile. The Old World monkeys (Cercopithecidae) are divided into two subfamilies, the Cercopithecinae and the Colobinae; the latter group is distinguished by a specialized stomach capable of digesting large quantities of mature leaves. Brief observations have been made of several species of Colobinae, but the only form studied in detail is the common langur of India and Ceylon, *Presbytis spp.* (Jay 1965). Among the Cercopithecinae, numerous studies have been made of the two closely related ground-adapted forms, the African baboon (*Papio*) and the Asian macaques (*Macaca*). Of the other two basic groups of

Cercopithecinae, the mangabeys (*Cercocebus*) and the guenons, or vervets (*Cercopithecus*), a long-term field study has been made of only one, a ground-adapted species, *Cercopithecus aethiops* (Struhsaker 1965).

The four apes, the Pongidae, are the gibbon (including the siamang), the orangutan, the gorilla, and the chimpanzee. All of the apes differ from the monkeys in that the trunk is "short, wide and shallow . . . the lumbar region is short . . . and the shoulder and arm muscles are especially adapted to abduction, flexion, and rotation" (Washburn & Hamburg 1965, p. 9). Because of this adaptation to climbing and the ability to hang or swing from branches, to brachiate, apes have a "vertical" posture, thus differing from the horizontal, quadrupedal monkeys, and it is no surprise that in their structure and bodily movements the apes closely resemble man. Physically, and to some extent behaviorally, man is most like the African great apes—the gorilla and the chimpanzee. But apes are confined to heavily wooded areas, and some of the behavioral patterns which have enabled man to travel long distances in open country are more closely paralleled in the behavior of terrestrial monkeys, such as baboons and macaques. In fundamental senses such as hearing, eyesight, and smell and in the organization of the brain, the viscera, and the reproductive organs man, the apes, and the Old World monkeys share a basic biological pattern which distinguishes them from all other mammals, including New World monkeys and other primates.

**Field studies of primates.** Although attempts were made to study the African apes soon after their discovery in the nineteenth century, most reports of monkey and ape behavior in the wild remained anecdotal until Carpenter observed the howling monkeys of Panama in 1931. In succeeding years, other field studies were attempted, but these were usually brief; then, in the 1950s, investigators in Japan, the United States, and Europe independently initiated a variety of field studies emphasizing long-term, systematic observation of primates living in natural habitats.

Most field studies have been made on monkey species that spend large amounts of time on the ground, where observation conditions are easiest. Because of their similarity to man, all the living apes except the orangutan have been the subject of at least one major field study. Long-term studies of free-ranging groups in monkey colonies have also contributed valuable data. The Japan Monkey Center has kept records of individual monkeys in its colonies since the early 1950s. Beginning with

Altmann in 1958 (see Buettner-Janusch et al. 1962), various investigators have restudied the rhesus monkey colony established on Cayo Santiago by Carpenter in 1938; in fact, since 1958 almost all the members of this free-ranging colony have been tattooed for identification. Because the life cycle of primates is so long, field workers cannot ordinarily ascertain sibling or mother-offspring bonds between adults, and yet these relationships are proving to be very important in some species. (For a more complete history of field studies see Southwick 1963, pp. 1–6; and Washburn et al. 1965.)

Laboratory studies of primates, especially of the common Indian rhesus monkey, have continued without interruption since the 1930s. Contemporary views of such topics as discrimination, operant conditioning, perception, and learning have been summarized by Schrier, Harlow, and Stollnitz (1965). Recent studies of hemoglobins, blood serums, chromosomes, the nervous system, and the skin have been reported by Buettner-Janusch (1963–1964). There are two journals devoted entirely to primate studies, *Primates* and *Folia primatologica*, and there are many films of primate behavior.

The formerly facile generalizations about monkey and ape behavior are no longer tenable. Although only about a dozen of the several hundred varieties of living primates have been studied to date, it is already clear that primates exploit a wide variety of ecological niches, that they live in different kinds of social groups, and that different species display quite different temperaments. Some species are distributed over large geographical areas, and group structure and behavior have been found to vary significantly between different populations of the same species (Jay 1968). The unique life history of every individual produces distinctive patterns of temperament and social behavior among the members of a single group. All of these variables make it inevitable that there will be important exceptions to many of the following generalizations.

### Primate group structure

Most vertebrate social groups undergo a variety of changes in group composition during the year. Changes are correlated with such phenomena as the abundance of food, the mating season, the birth season, and the maturation of offspring. During the mating season adult males may drive off young males and form harems of receptive females; mothers may leave the group altogether when they give birth, living apart until their off-

spring are able to support themselves, or females with immature offspring may form separate bands of their own. Some or all of these groups may participate in seasonal migrations. The result is a "population" with changing aggregations of individuals during the yearly cycle.

The social group of the Old World monkeys and the apes is very different. Membership in the social group is usually continuous, and group composition may remain stable over many years. Typically, an individual is born, matures, leads its adult life, and dies in the same group. While there are interesting exceptions to these generalizations, they are so characteristic of a wide variety of monkey groups that it is convenient to speak of a distinctive group organization, the "troop." A troop so defined is a group of several adults of both sexes, together with juveniles and infants, which maintains a social identity and spatial unity that persists through the annual cycle and transcends the life-span of individual members. Such a troop is easily recognizable to the field observer because its boundaries are typically defended against outsiders. This social organization describes the basic social group of such Old World monkeys as lan-

gurs, baboons, macaques, vervets (*Cercopithecus aethiops*), and colobus; of the New World howling monkey (*Alouatta palliata*), and perhaps spider monkeys (*Ateles geoffroyi*) (see Table 1). Less complete studies suggest that this type of group organization may also be characteristic of at least some species of mangabeys and some other species of *Cercopithecus*. The troop is also characteristic of *Lemur macaco* and probably of some other species of lemur. The description of the troop would apply to the social organization of the mountain gorilla, except that members may move in and out of some mountain gorilla groups rather freely.

Old World monkey and gorilla troops average about 25 individuals, but normal groups may be as small as 10 or number more than 200. The fact that primates normally remain in one social group throughout the year means that group members with needs and motivations as different as a small, helpless infant and a large, potentially dangerous adult male must accommodate each other. Among most vertebrates, when antagonisms arise between adults or between adults and mature offspring, usually during mating or birth periods, the result is a change in group structure. In some pri-

Table 1 — Types of social groups among primates

c. Changes during daily cycle.

d. Geographical variation.

mate species young adult males may change groups or live for a time in an all-male group or as solitary animals. But most remain in their natal group, where mutual tolerance and group cohesion are accomplished by such different behavior patterns as the dominance hierarchy, the persistence of mother-offspring bonds into adult life, an elaborate repertoire of affective communication, and the conservative tradition of the group. In such groups each individual has a status with regard to every other individual, and through the long period of infancy and adolescence, the individual learns to anticipate the responses of other group members and behave accordingly. It is in the rich behavioral context of these Old World primate social groups that many of the behaviors which we have come to consider "human" were first developed.

In patas monkeys (*Erythrocebus patas*), hamadryas baboons (*Papio hamadryas*), and geladas (*Theropithecus gelada*) the basic social unit comprises several adult females and their offspring but only one adult male. Still another primate grouping pattern is the mated pair with offspring, reported to be found in the Indridae, in some small South American monkeys, and in the gibbon. This form of social organization has been compared to the human family, but it is actually the result of very different behavior patterns. An adult gibbon, for example, is antagonistic toward all other gibbons except its mate and its immature offspring. As a result, each gibbon pair lives apart from all other pairs, and even their own offspring are apparently driven away at maturity. In this respect the gibbon group is more comparable to a mated pair of birds during the breeding season than it is to the human family. (Unlike most birds, the gibbon group is stable and unaffected by seasonal variation.) The human family cannot occur as an isolated pair of adults but is always a subgroup within a larger social unit.

Most of the prosimians are small, arboreal, nocturnal creatures which, like many other such mammals, forage as individuals, coming together only rarely. Yet some, such as *Propithecus verreauxi* and some species of lemurs (such as *Lemur macaco*), live in small troops. The small galago or bushbaby (*Galago senegalensis*) forages singly at night but may sleep in small groups during the day and form mated pairs during part of the year. (The most complete discussion of the classification, social groups, and activity patterns of Madagascar lemurs is in Petter 1962 and is summarized in Buettner-Janusch et al. 1962 and in DeVore 1965a.)

Still another form of social group is described for the chimpanzees by Goodall (1965) and by

Reynolds and Reynolds (1965). Small subgroups of a population, such as females with young, adult males, and mixed groups of males and females, roam freely in a local area of forest. These clusters are in frequent contact and may gather together, for example, at food trees but do not appear to be organized into large persistent social units. On the other hand, recent observations of chimpanzees by the Japan Monkey Center personnel suggest a group size and organization much like a monkey troop: when crossing open country between forest patches, the chimpanzee group consistently numbered 43 and contained a nucleus of adult males, females in estrus, and females with infants. On the basis of brief observations some monkey species, especially in the New World, may also live in loose aggregations. The aggregations of hamadryas baboons are different in that the one-male units remain intact even though more than seven hundred individuals may gather at the same sleeping place (Kummer & Kurt 1963).

As a result of field studies in progress, it will soon be possible to refine the descriptive categories shown in Table 1 and to add many new species. While the table reveals certain trends, such as the solitary life of many nocturnal prosimians and the frequent occurrence of the "troop organization" in monkeys, it also illustrates the difficulty of abstracting a model of "monkey" or "ape" social organization. Further, gross categories such as those in Table 1 should not obscure major behavioral differences: the frequency, intensity, and complexity of social contacts among members of a lemur troop are far fewer than comparable contacts among members of a monkey troop. This list of primate species could be tabulated with respect to characteristics such as habitat, diet, and group size (Crook & Gartlan 1966). For example, with the possible exception of some prosimians, males of all these species are dominant over females, and this is broadly reflected in the degree of sexual dimorphism they display. There is great variation in this characteristic, ranging from the gibbon, in which the sexes are scarcely distinguishable in size, to the baboon and the gorilla, where the male may be two or three times as large as the female. Sexual dimorphism with respect to body size, size of canine teeth, and general robustness of the skeleton and musculature all tend to correlate with the extent to which a species is adapted to the ground. Indeed, the degree to which an Old World primate species is adapted to life in the trees or to life on the ground is one of the best ways of predicting the size of the group, the degree of sexual dimorphism, the intensity of dominance relations among

adults, the use of loud vocalizations in intergroup spacing, and the size of the area over which the social group ranges ( DeVore 1963 ).

### Dominance and aggression

"Dominance" has been defined in many ways by different workers, and further study will undoubtedly show that quite different behaviors have been subsumed under this rubric. Common to all concepts of dominance, however, is the notion that the dominant individual can assert priority over a subordinate in order to gain some desired objective. Although expressions of dominance vary widely from one species to another, between groups within the same species, and even in the same individual at different times, it is clear that dominance interactions are fundamental to primate behavior and that they are especially prominent in the Old World monkeys, apes, and man. It is in the primarily ground-dwelling species such as baboons and macaques that dominance behavior is most apparent, and it is in the social groups of these species that dominance hierarchies exert the most influence in social organization. In these monkeys an adult male is about twice the size of an adult female, and there is typically a pronounced gap between the bottom of the male dominance hierarchy and the top of the female hierarchy. In more arboreal species, females are usually more nearly the size of males, and the dominance hierarchies of the sexes may overlap to some extent. In such species expression of dominance is often less frequent and more subtle, and mere avoidance, for example, may be as important as a challenge or attack in the demonstration of dominance status. In one-male groups the male is larger and more dominant than the females and does not tolerate any other adult males. In the loose aggregation of a species like the chimpanzee, there are frequent dominance interactions between adults, but it has not been reported whether these result in a hierarchy such as gorilla groups show.

The rank of any individual in a dominance hierarchy was formerly considered to be the result of the success of that individual in dominance interactions with each of the other individuals in the group. However, from recent studies of Old World monkey and ape groups, it appears that dominance status is seldom, if ever, simply the outcome of an interaction between two individuals. Any of a series of circumstances may intervene in the free expression of dominance between two individuals. The mother comes to the aid of her offspring during childhood and, at least among rhesus monkeys, into adult life as well ( Sade 1965 ). Other individ-

uals frequently join the combatants when a fight starts, and adults who tolerate each other will often support each other when one of them is challenged or attacked ( DeVore 1965b ). Thus, an individual's dominance status is the result of a variety of factors, including past success in dominance encounters, the status of its mother, and the number and status of the individuals who will support it when challenged.

**Threat behavior.** Baboons and macaques, among whom thresholds of aggression are lowest and agonistic encounters most frequent, exhibit the most elaborate repertoire of gestures and vocalizations conveying anger, threat, and fear. One form of threat behavior which is common in all the Old World primates ( including man ) is the "redirection of aggression," in which one animal threatens another and the threatened animal redirects the threat to a third individual or even to an inanimate object such as a stone or branch. For example, the loser of a fight between two adult males may chase a more subordinate male or a female or he may shake a tree limb vigorously. If he has chased a female, she will often chase or threaten a more subordinate female or a juvenile. This chain reaction of aggressive acts probably serves to periodically reinforce the various dominance statuses of all the participating group members.

**Male dominance.** Dominance relationships among adult males in baboon and macaque groups are often stable over many months or even years. A male's status is ultimately based on his strength and fighting ability, and unless the group is very large, the males tend to be arranged in a linear hierarchy, or "peck order," in which each male is dominant over all individuals beneath him. This stable hierarchy of recognized status serves to reduce the number of agonistic interactions among males. In some savannah baboon, rhesus monkey, and Japanese macaque troops, several males in their late prime may be so tolerant of each other that dominance between them is rarely expressed, and in such troops these males may constitute a nucleus in which the members support each other in dominance interactions. As a result, these older males, some of whom would lose a fight to a younger male in individual combat, are able to hold the young males in check by combined action ( DeVore 1965a, pp. 54-71; Imanishi 1960 ). It is this nucleus of older supporting males that takes the initiative in protecting the group from outside danger, in repelling individuals who try to join the group, and in breaking up fights among group members. On the contrary, among gorillas and in small monkey groups this initiative is taken by a

single dominant, "alpha" male. Dominance behavior is difficult to understand in captivity, where it seems to be disruptive and antisocial. But in natural surroundings, dominant males protect weaker group members, and females and juveniles seek out the dominant males to sit beside or to groom. So, although the dominance hierarchy depends ultimately on force, it leads to relative peace and stability within the group.

**Female dominance.** The dominance hierarchy of females tends to be unstable and to depend to some extent on the female reproductive cycle. Females in estrus are more active and aggressive and are frequently under the protection of a consort male. Among baboons and macaques, adult males are extremely protective of young infants, and this protection also extends to the mother as long as she is with a young infant. Thus, although it is clear that some adult females are more dominant than others in almost all circumstances, the interference of reproductive cycles in female-female dominance interactions seems to preclude the establishment of stable, linear dominance hierarchies.

### Sexual behavior

As in humans, most female monkeys and apes have a menstrual cycle of about thirty days. Because humans do, and monkeys in captivity may, breed at all times of the year, the belief has been widely held that Old World primates show no seasonal variation in mating activity. Since the publication of Zuckerman's *The Social Life of Monkeys and Apes* (1932), it has often been asserted that the basis of monkey and ape societies is sexual attraction; however, we now know that the nonhuman primate group performs many functions besides providing its members with sexual outlets.

There are many differences in patterns of sexual behavior between man and the nonhuman primates. In the first place, in at least some species of macaques, there are sharply defined mating and birth seasons. The data are best for the Japanese macaque and for the rhesus on Cayo Santiago, where records have been kept longest. Lancaster and Lee (1965) show that Old World monkeys tend to have at least a birth peak, if not a sharply defined birth season. Most monkeys give birth every year, and as in many birds and mammals, their reproductive cycles are presumably affected by such phenomena as day length and temperature. The reproductive cycle of some species, such as the baboons and the apes, is longer than a year, and if marked seasonality of sexual reproductive behavior

exists in these species, it has not yet been demonstrated.

Another reason that opportunity for mating is an inadequate explanation of social cohesion in nonhuman primate groups is the fact that the female is sexually receptive for a relatively small portion of her life. Females will accept a male only on those days of their sexual cycle when they are in estrus, and sexual cycles are inhibited during pregnancy and lactation. Females and their young constitute the core of monkey groups, and yet the amount of sexual activity in the life of any female, or within any group during the year, is very small. In a species with a mating season, disruptions are most common during this season. At this time extragroup males attempt more actively to join the group, and the existing competition among males already in the group may become more intense. Koford (1966) reports that on Cayo Santiago 66 per cent of all rhesus males who leave a group do so during the mating season. One of the Cayo Santiago groups subdivided into five groups between 1958 and 1964, each subdivision occurring during the mating season. On the other hand, social bonds within groups are probably strongest during the birth season, when mothers are clustered together with their new infants and adult males are actively caring for the infants of the previous year.

**Mating patterns.** In such species as the gibbon and the patas monkey (and in small groups of any species), only one adult male does the mating, but in most Old World primate groups the female is potentially accessible to every male in the group during some part of her estrous cycle. In such dominance-oriented species as baboons and macaques, the tendency is for the most dominant male to have priority of access to an estrous female, but his mating activity is usually confined to her period of maximum receptivity. For example, a female baboon is receptive for about 12 days in a thirty-day sexual cycle; the degree of receptivity can be gauged by the amount of tumescence in the sexual skin of the perineal area. During the early period of swelling she is mounted by juvenile and subordinate adult males, and it is only when tumescence is at a maximum that she is sought out by the dominant males. If there are a number of adult males of approximately equal dominance and only one receptive female, the males may threaten and fight for her possession. Although copulations early in her cycle are casual and transitory, dominant adult males usually form a consort pair with a receptive adult female. The pair may remain together for several days, or if there is competition among the

males, the pairing may be interrupted after only a few hours. A baboon male's ability to maintain possession of an estrous female when he is being threatened will depend in part on the support he can expect from other males (DeVore 1965b). The female must cooperate with the male during copulation, and she is thereby able to exercise some personal preference and to take some initiative in making sexual contacts. Thus, mating patterns in even a sexually dimorphic species like the baboon are more than a simple reflection of the male dominance hierarchy. There are opportunities for subordinate males to copulate before the female becomes attractive to the dominant males; a male's ability to mate may depend on his relationship to other, supporting males; and the female herself is able to exert some initiative.

### Prolonged immaturity

By comparison to other mammals of similar size, the period of infant dependency is remarkably long in primates, and the necessity for providing care and protection of immature offspring is a dominant feature of monkey and ape social life. Ordinarily an infant in danger is retrieved by its mother, but adult males of many varieties of monkeys will threaten, distract, or attack a potential predator. Aggression toward predators is most prominent in ground-dwelling species such as baboons and macaques; for example, on an average day a baboon group may range as far as two or three miles from the safe refuge of trees.

The birth of an infant not only changes the quantity and quality of its mother's social interactions, but every member of the group is affected in some measure. Adults and juveniles are highly attracted to young infants and repeatedly approach them to inspect, fondle, groom, and play with them. The newborn infant primate clings to its mother at all times, imposing substantial behavioral constraints not only on her but on the entire group. This prolongation of preadult life is so biologically expensive for the species that there must be major compensatory advantages. In a recent discussion, Washburn and Hamburg (1965) have suggested that this prolonged period of immaturity makes it possible for the species to adapt to a wide variety of environmental contexts because of the opportunity it provides for complex learning in the young. A large number of laboratory and field studies support the fact that much of the normal adult behavior of the species must be learned. In nature immature monkeys are in frequent contact with adults of both sexes and with their peers. The

major activity of the young primate is "play," and it is during these long hours of daily play that the juvenile learns both the features of its physical environment and the appropriate responses to the other animals in its social environment. The development of normal sexual behavior, the expression of effective patterns of affection and dominance, and the ability to rear an infant competently are all social skills which must be learned, and monkeys raised in isolation show major deficits in all of these behaviors (Harlow & Harlow 1965; Mason 1965). Social deprivation experiments also indicate how even less drastic events in the early life of a young primate reared under normal conditions may lead to the striking individual differences in adult temperament and social skills that are so frequently reported by research workers.

**Mother-offspring relations.** It has long been obvious to observers that the relationship between a mother and her offspring is the most intense and prolonged in primate life. During the usual field study it is impossible for the observer to know what genealogical relationships may exist between adults or between any group members who are beyond the weanling stage. Rejection by the mother when she weans her infant seems so firm, and the effect on the infant so traumatic, that the tendency has been to assume that their early close bonds have been severed permanently. (Moreover, the mother's attentions are soon redirected to the care of another newborn infant.) But these conclusions are clearly incorrect, at least for some species, as prolonged observation of identified individuals has shown. Studies reported by Imanishi (1960) and Koford (1963) indicate that the rank of a young male in the dominance hierarchy is frequently very closely related to the rank of his mother; high-ranking mothers tend to rear high-ranking male offspring. The evidence is less clear for females, but it seems likely that high-ranking females may also be related as siblings or as mother and daughter.

Sade (1965) has offered the most detailed accounts of the importance of social bonds between uterine kin in rhesus monkeys. The most frequent subgroups are clusters of mature and immature offspring around an old female. These animals not only sit together and groom each other more often than they do other group members, but they frequently support each other in dominance interactions as well. Data indicating the importance of genealogically related subgroups are most convincing for the Japanese macaque and the rhesus on Cayo Santiago, where individual records have been

kept for many years, but Jane Goodall (1965) has also described similar clusters of offspring around old female chimpanzees. Troops of Japanese macaques and rhesus monkeys which contain no adult males (except during the mating season) have been reported, but they are rare.

The achievement of high rank by the offspring of dominant females appears to be caused both by childhood experience and by the mother's support of her mature offspring. Infants of dominant females stay with their mothers and other dominant individuals near the center of the group, and in the Japanese macaque they may never go through the period of social peripheralization that is characteristic of most young males. They are born in the middle of the group, grow up there, and remain there as adults, assuming at a young age the roles peculiar to the dominant males at the heart of the group. Also, in day-to-day agonistic interactions, a young male who is supported in aggressive encounters by a dominant mother will simply win more of these encounters than one whose mother is subordinate. Presumably the long period of conditioning during infancy and adolescence strongly reinforces a male's expectation of success or failure in the social dominance interactions of adult life. The question of the effect of genetic inheritance on the achievement of social dominance should be investigated; this could easily be done by cross-fostering experiments, in which the offspring of a subordinate female and a dominant female would be exchanged at birth.

Sade reports that rhesus mothers on Cayo Santiago continue to support their adult sons in dominance interactions with other group members. Furthermore, a mother ordinarily remains dominant over her son all of her life. Apparently correlated with this behavior is the fact that copulation between mother and son is very rare. In one of the few known cases of mother-son incest, the two had engaged in a vicious fight, and the son had subsequently become dominant over his mother before the mating occurred. Although they are not yet well understood, it appears that the complicated patterns of nurturance and dominance behavior between mother and son may inhibit copulation between them and that the aversion to incest may be present among members of a number of Old World primate species.

**Adult male-offspring relations.** Paternity in nonhuman primate groups is rarely known or knowable either to the investigator or to the monkeys. Adult males seek to protect *any* infant from injury either from group members or from predators. However, in some species an adult male may

form a special protective relationship with a particular infant. In the Japanese macaque, for example, males frequently establish such a relationship with yearlings when these are rejected by the mother and replaced by a new infant (Itani 1959). Analogous behavior has been reported in other macaques and baboons (Washburn et al. 1965). Among some New World marmosets a male may carry an infant at all times except when the mother is nursing it. The one-male unit of the hamadryas baboon develops because young adult males forcefully adopt immature females, "mothering" the females until they reach sexual maturity (Kummer 1968).

There are no indications from field studies that the adult male in *arboreal* Old World primates establishes strong social bonds with infants or juveniles beyond protection of infants when the group is threatened by a predator. Even in the ground-adapted patas monkey and in the vervet monkey, the role of the male seems limited to protection or to distracting predators, and the present evidence indicates that more elaborate male-offspring relations arise only in terrestrial primates living in large social groups.

### Human and primate social organization

Only a few years ago nonhuman primate behavior was assumed to be simple, stereotyped, and easy to observe; with notable exceptions (Carpenter 1964), field reports were largely anecdotal accounts by casual observers. Observations of zoo colonies suggested that primate groups were a disorganized rabble, tyrannized by aggressive males and held together only by sexual attraction. From the perspective of modern field studies, the conclusions based only on the behavior of primates in captivity bore as little relation to the social organization of free-ranging groups as would a monograph on middle-class society based solely on a study of inmates in a maximum-security prison.

Social organization is not identical for any two primate species. Human social organization, with its varied cultural manifestations, is unique; but studies of monkeys and apes are helping to distinguish those behavior patterns that are truly unique from those which man shares with his nearest relatives. Before the urban revolution human social organization was centered on small, face-to-face groups of adults involved in the quest for food and the protection of immature offspring, and it is not surprising that patterns of dominance and aggression and of nurturance and affection seem so similar in men, monkeys, and apes. The division of labor by sex, with females specializing in child

care and males as protectors, and the performance of different social roles according to status are familiar patterns to the sociologist. The evolutionary basis of man's unique biological and social system is treated elsewhere in this encyclopedia, but it seems appropriate to outline here some of the features of human organization which seem to distinguish men most clearly from the other primates [see EVOLUTION, article on HUMAN EVOLUTION].

Much of the contrast between human and primate social organization is based on human language. Communication in monkeys and apes is a rich complex of vocal, gestural, and tactile signals, but the majority of these signals are reflections of changing emotional states among the communicants and are comparable to the communication systems of other animals, not to language [see COMMUNICATION, ANIMAL; see also Marler 1965; Bastian 1965; Altmann 1967]. Language is so fundamental to human life that it is impossible to dissociate it from other distinctly human behaviors, such as toolmaking and the willingness to share food. Nonhuman primates do not share food, even with their own infants, but neither do they have tools to gather food or an improved site or camp from which they can disperse during the day in complementary gathering and hunting activities and where they can convene again to share the results of the day's quest.

The most distinctive feature of human social organization, the family, is adaptive only in the context of an economy based on tool use and sharing; presumably it also requires other uniquely human traits such as the ability of the female to mate at all times. On the other hand, many behavior patterns that have been viewed as ramifications of the human family are actually present in the Old World primates—the maternal affectional system and its extension to uterine kin, the close association of siblings, the protection and nurturance by adult males of the young—and it is no longer so difficult to understand how the human social systems could have evolved. With language, an incest aversion between mother and son became an incest taboo; with language, the already close ties among uterine kin were explicitly recognized and socially extended.

Field and laboratory studies of primates were not begun on a large scale until the 1960s, but they are now attracting the attention of persons in biology, ethology, and all branches of the behavioral sciences. Techniques of observation and analysis are constantly being refined, and behavioral studies are being combined with experiments in pharma-

cology, hormonal studies, and neurophysiology (Washburn & Hamburg 1968). For example, miniature telemetering devices implanted in the animal have been used to record and direct the behavior of individuals in a free-ranging group. Ethological principles and techniques of observation are being applied to humans and the results compared to studies of nonhuman primates [see ETHOLOGY]. There is every indication that in the next few years this renewed interest in the nonhuman primates will yield results of increasing relevance to the social sciences.

## III

## THE REGULATION OF ANIMAL POPULATIONS

Ecologists have been studying the dynamics of animal populations for roughly forty years, trying to discover how their numbers are regulated. The subject is of much practical importance in a world in which man, either knowingly or unknowingly, interferes drastically in this process and in which our own exploding population has become a central threat to human survival. Scientific knowledge in this field has reached a stage at which generalizations are possible, although final agreement has not been reached.

Populations of animals obviously cannot all have the same life-cycle characteristics. Many of the insects run through several generations in a single summer, after which the population remains dormant during the winter and regenerates in the spring. Larger forms of animals, on the other hand, tend to live longer, and most of them have populations that keep going all the year round. Some populations fluctuate in numbers from season to season; others remain practically constant from year to year, even from decade to decade. Striking examples of the fluctuating kind include the arctic lemmings, many of the northern game birds and fur bearers, and the subtropical locusts. The steady state typically applies to most kinds of big game, many birds, and other animals both large and small, especially in temperate and tropical regions with equable climates. There is a continuous gradation between the extremes, and under natural conditions the populations of most animals in most situations resemble one another in one very important respect, namely, that there is no long-term trend either up or down.

The normal situation is one in which the density of population moves or fluctuates irregularly, either weakly or strongly depending on circumstances, to a varying distance on either side of a constant average value. If and when permanent changes

take place in the environment, the average is also likely to shift and will assume a new level once the environmental change is complete. Therefore, we need to find out what determines the average, what causes the fluctuations and prevents them from swinging out of control in one direction or the other until the population either approaches infinite size or falls to zero.

**Population income and loss.** Animals must in general possess the fecundity necessary to augment their numbers; otherwise they would quickly die out. In the course of time local populations receive an *income* of new recruits, largely as a result of reproduction, although some may come through immigration. They are also subject to *loss*, some of it by emigration and the rest through mortality. If the population stays roughly constant in number over the years, it means that the cumulative totals of recruitment and loss have balanced out.

The fact that populations tend to maintain a constant average level and that when fluctuations occur they do not proceed very far in one direction or the other without being checked indicates that there must be some stabilizing process at work. For example, if the recruitment rate were always 20 per cent per annum and the death rate 25 per cent, the population would steadily diminish to the vanishing point; similarly, if the two rates were reversed, it would expand at 5 per cent compound interest. But let these rates vary according to whether the population density is high or low—so that high density produces low recruitment or high mortality or both, and low density the opposite—and then any continuous trend of numbers up or down can always be prevented. The phenomenon typically found in nature, of population density balanced within relatively narrow limits of variation, cannot in fact be accounted for in any other way than by regulators that operate in this manner and are “density dependent” in their action.

There is one important school of thought which believes that density-dependent action arises mainly from the factors causing losses in the population. According to this hypothesis, animals are supposed always to reproduce as fast as they efficiently can, the surplus so produced being removed in a density-dependent manner by the various destructive agencies, namely predators, parasites and disease, starvation, and accidents of the physical world, such as floods and droughts. On the face of it, there seems nothing impossible or improbable in this: disease, for example, would be expected to spread fastest in overcrowded conditions, and starvation would have a similar incidence. The

rate of accidental mortality seems perhaps the factor least likely to have any connection with population density.

There are, however, many large animals, of which primitive man was a good example and lions and eagles are others, which effectively have no predators and appear not to be regularly subject to death from disease on a significant scale, except perhaps among old or outcast members of the population. We find ourselves, therefore, forced back on starvation as the only remaining density-dependent agency that might be capable of removing a population surplus. This possibility calls for close examination.

Population density clearly has a very special relationship to food supply. Animals “select” their environments or habitats in accordance with their natural inclinations. The habitat selected has to provide them with the resources they need for sustaining life, including food of adequate quantity and quality, space, shelter, and breeding sites. In the great majority of species, food is the resource that sets the upper limit on population density, and determines the “carrying capacity” of the habitat. Habitats can therefore generally be graded as richer or poorer almost entirely in terms of their food productivity, and the average population density of animals living in them has been shown, in situations where both can be measured, to be closely related to it.

However, the correlation between food supply and population density has no direct connection with starvation. The normal condition is that all individuals living in a particular habitat get enough to eat. If starvation occasionally occurs, it almost always comes as an emergency resulting from an accidental cause, such as exceptional cold or drought, and is not in any way dependent on the density of population that happens to be affected by it.

**Food resources harmed if overtaxed.** Human experience in exploiting purely natural resources of animal and plant life, whether they happen to be the virgin pastures of the prairies or fish or game, shows that most of them can all too easily be overtaxed. Persistently overgrazed pasture quickly deteriorates and especially in arid climates can be reduced to a worthless desert in a few centuries. If we take too big a crop from our fisheries, whether for commerce or sport, or press too hard on fur bearers, wild fowl, or game, the stocks and the yields decrease. Unfortunately, long after the demand has become excessive, it is almost always still possible to go on making money, and we tend therefore to shut our eyes to the in-

creasingly disastrous consequences piling up for the future. This highly characteristic danger inherent in the exploitation of "recurrent resources" has often led in the past to the decimation of the more lucrative and vulnerable prizes of the hunter, such as the passenger pigeon, the northern right whale and the blue whale, the fur seal and marine turtle, or the rhinoceros of Africa and Asia, now threatened because their horns are highly valued by people in the Far East for their supposed aphrodisiac powers.

In exploiting their own sources of natural food, animals face exactly the same dangers as man. For the same reason, therefore, they must exercise restraint while there is plenty, if that plenty is to be conserved and future yields sustained.

This is a deduction of great importance, for it implies that starvation can be ruled out as a practicable means of curbing population growth. Long before starvation occurred, disastrous damage would have been done to the food resource by over-exploitation, and the survival of the entire population would be threatened.

It can be concluded, therefore, that not only are there many kinds of animals which are not subject to predation or disease on an effective scale, but that starvation can also be eliminated as a practical regulating factor, because damage to the habitat is a precondition and, consequently, constitutes a continual threat to the safety of the group as a whole.

### Regulation through "conventions"

It is now necessary to explore the alternative hypothesis that animals themselves possess the means of controlling numbers and population density. If they were able to do this, it would obviously be an adaptation of great value, because an ability to control population density would imply that it could be adjusted to some particularly favorable level, and that level could very well be the optimum one, as far as exploiting the food resource is concerned. Ideally, it would then be possible to take the maximum sustainable crop from the food resource and always feed the largest number of mouths that could be safely allowed without ever running the risk of overtaxing or depleting the supply.

It is a common situation for an animal population to depend for a period of weeks or months on a standing crop that is not at the same time being replenished. This applies, for example, to birds feeding on seeds and berries in the fall or hunting for hibernating insects during the winter. When they first broach the food stock, it is at

maximum abundance and for perhaps hours or days could provide food for a prodigious number of exploiters. But it must be made to last much longer than that, and somehow the number or population density of exploiters must be restricted from the outset. The food itself will not restrict them, because it is superabundant; and yet the reason for imposing the restriction is related to food and food alone. What is required is some artificial method of limiting the population density, one that is, if possible, closely correlated with food production, serving as a buffer or shield in preventing overexploitation: something, in fact, closely analogous to the restrictive conventions entered into by states and nations to prevent commercial overfishing in the sea.

It is at once apparent that a great many conventions of this kind exist in the natural world. The best known of them is the territorial system adopted by many kinds of birds during the breeding season. In the case of robins, cardinals, song sparrows, and a host of other birds, the males of a species compete with each other, each claiming and defending a territory on which pairing, nesting, and rearing of a young family subsequently take place. The males will not tolerate the crowding of territories beyond a certain limit, so that once a particular habitat has been taken up in claims, no further males can get in; any that attempt it are soon forced to leave and try somewhere else.

This is a perfect example of a conventional density-limiting mechanism, and one easily understood. What has happened is that direct contest between rival members of the group for actual food has been sidetracked into equally furious competition for a piece of ground—a conventional substitute. Once the ground is "owned," the owner and his dependents can use the food that the territory contains in perfect freedom, without further dispute, and provided the conventional territory size is large enough, there need be no danger that their demands will overtax the supply.

In a short article one cannot hope to do more than suggest the broad implications of this hypothesis. It must suffice to say that many of the density-limiting conventions that can be observed in nature are less direct or more sophisticated than the simple territorial one. For example, birds that depend on the resources of the ocean cannot stake individual territories for gathering or nesting on the sea itself. Instead, they breed in a colony on shore which in most cases is quite artificially limited in size and in which each successful pair gains a token territory in the form of a small nest

site. Adults that have not succeeded in winning a nest site take on the status of onlookers and are frequently found at seabird colonies. They are evidently inhibited from nesting outside the traditional boundary or from starting a new colony around the corner. This conventional recognition of a colony is presumably related to the food supply, limiting the local population to a size that will be permanently immune to overfishing; however, as compared to the territorial system, the form it takes is more abstract or artificial because the object competed for is reduced to a few square feet or a hole or crevice, rather than the entire food-supplying territory. Abstraction can go even further than this. In some cases it is only the right to membership in a group that is recognized; the alternative is rejection as an outcast. Thus, there may be no contest for actual property at all, but only for individual or personal status.

These conventions are normally concerned with competition between the members of the population of a single species of animal: that is to say, with intraspecific competition. This competition provides conventional goals or rewards that are substituted for actual food, and their effect is to limit the number (or density per unit of food) of members in the group and to unload any unwanted surplus to a safe distance.

It is important to note that the competition itself assumes artificial or conventional forms. Birds contesting for territories seldom fight and kill each other, although winning a territory can in fact easily be a matter of life or death as far as the respective consequences to the victor and vanquished are concerned; instead they sing and threaten by voice or display fine crests or splendid or startling patterns of plumage.

Social behavior provides the key. It takes but a short step at this point to reach the most striking and important generalization to emerge from the new hypothesis: Any group of individuals competing for conventional prizes by conventional methods automatically constitutes a society. Behind this there is the deeper implication that here is the essence or root from which all social behavior has stemmed: that the evolution of a primordial social organization occurred as an adaptive mechanism for the control of population density. A *society* could be defined as an organization capable of providing conventional competition among its members; in these terms, sociability is seen to have a biological basis. One does not need to ponder very deeply to see how closely this cap fits even in human social groupings, where leaders emerge even though individuals need not be engaged in

any direct form of competition. A society, whether human or animal, is in essence a brotherhood tempered with rivalry.

Inasmuch as it incorporates the mechanisms of competition, social organization appears to be indispensable in the process of maintaining an optimum population density. This is readily apparent in a territorial system, like that of birds, where neighbors of the same species are in constant social competition and by their behavior directly control the population density in the habitat. The long-term research on the Scottish red grouse being carried on near Aberdeen has shown, for example, that the grouse population on a heather moor consists of individuals all mutually known to their neighbors and greatly different in social standing. Dominant cock birds hold territories almost all the year round, covering the habitat like a mosaic; the most aggressive have the biggest territories. Socially subordinate cocks and unmated hens are often carried as members of the population although there is no room for them to establish any territorial claims for themselves. With the onset of winter, or when the productivity of the food supply declines for any other reason, it is the subordinates at the bottom of the social ladder that get squeezed out, leaving behind a surviving group adjusted in density to suit the lowered food level.

The social hierarchy, or peck-order system, thus works as a safety valve, or overflow mechanism, identifying and unloading those who cannot be supported when there is a drop in food supply. If the population were not thinned down in this way, damage would be done to the habitat by overtaxing the resource. By means of the social hierarchy not only is damage prevented but the remaining population is assured of an adequate diet and a reasonable chance of survival.

The hierarchy also operates in relation to breeding. Only established territory owners and their mates can breed, although unestablished non-breeding adults can still be carried in the population and form a valuable reserve to fill any gaps that appear in the ranks of the establishment. It may be noted that the hierarchy is another well-known biological phenomenon for which no general functional explanation has been given, although it finds an automatic place under the new theory.

Characteristically, red grouse compete under conventional rules, one of which is that, at least in the fall, the competition takes place only between dawn and about 8 A.M. After that the social groups flock amicably, and all feed side by side for the rest of the day. So fierce is the aggression among

the cock birds at dawn, however, that it is enough to subject some of the less-spirited competitors to a stress that not only drives them away from the habitat altogether but leaves them defenseless to predators and liable to succumb quickly to disease.

The convention of competing at dawn, and often at dusk, and leaving the rest of the day free for other necessary activities like feeding is exceedingly common and appears to shed a flood of light on the timing of such familiar phenomena as the cockcrow and the dawn chorus of birds, the dusk flighting of ducks, the massed maneuvers of starlings and blackbirds at their roosts, the synchronized choruses of some kinds of tropical bats and cicadas, and the activity of marine life such as the croaker and the snapping shrimp; there are innumerable other analogous phenomena in which an indication of present numbers seems to be provided through synchronized communal activity. Dawn and dusk are of course the two most easily perceived hours of the day, and this no doubt explains their wide use for brief social activities that call for a simultaneous general participation in order to achieve their effect.

**Homeostasis and epideictic feedback.** Community displays and contests provide the essential index of population density from day to day, producing "information" which can lead to an appropriate response when an adjustment to density is required. The whole process of balancing the population against the changing food productivity of the habitat appears to be a "homeostatic," or self-stabilizing, one, based on a feedback of information that sets the wheels of the adjusting machinery in motion whenever the balance has swung away from the optimal level. Community displays can not only lead to the expulsion of a population surplus, as in the case of the red grouse, but when the breeding season comes round, they can also serve to indicate how large a quota of recruits will be required to replenish the population or build it up to the particular level that is justified by the current carrying capacity of the habitat.

We need a technical term to describe this kind of activity, whose purpose is to sample population pressure, and "epideictic" has been chosen as having the right derivation and meaning. One could easily predict that epideictic displays would be especially conspicuous before the breeding season, when the population is about to be built up to its annual peak level; indeed, this is the time at which some of the displays already mentioned reach their height.

At that time in many species only the males are

required to take part in communal displays, each commonly acting as the representative of a mated pair; the females are otherwise occupied, frequently in more domestic duties. In these circumstances the males can be described as the "epideictic sex." The stimulation they receive from competing with rival males or sharing in exciting communal activities is density-dependent in its intensity: the more males there are, the hotter the pace. Rather frequently they assemble in unisexual swarms or groups, dancing in the air, perhaps, if they are flying insects or taking part in ritual tournaments, gymnastics, or parades, in the case of sage grouse and prairie chickens, tropical hummingbirds, manakins, and birds of paradise. They may have special vocal organs, as in songbirds, cicadas, frogs, drumfish, most crickets and katydids, howling monkeys, and many others. These are primarily used not to woo and win females, as was formerly thought, but to gain the prizes of social competition in the form of real estate and personal status. Exactly the same use applies to adornments, weapons, and scent glands. Much rethinking is therefore required on the hitherto vexed subject of sexual selection.

Epideictic displays are especially prominent among migratory animals as a prelude to their departure and as a means of smoothly handling heavy traffic over the vast tracts of country that often separate summer and winter quarters. This is especially true of birds. Without such displays the food resources would tend to be dangerously overtaxed in congested stopping places. The excited flocks of swallows and swifts, the spectacular massed maneuvers of locusts building up for a great emigration flight, and many of the big gatherings of birds, fruit bats, and insects to nightly roosts are associated with impending changes in population density through migration.

## Conclusions

In the light of this theory of self-regulation of animal populations effected through the agency of social conventions, we can turn back once more to the original questions and see how they have been answered. The average population level would appear to be set for most species by the size of sustained crop that the food resources can yield, and this level is actually achieved through a code of conventional behavior that prevents the growth of population from going above the optimum density. Some fluctuations in population level are produced by accidental events in the environment, including predators and disease, which may cause

extensive mortality; but in most cases they appear to arise from the operation of the homeostatic machinery, which automatically allows the population density to build up when resource yields are good and thin down when yields fall below average.

The homeostatic machinery responds directly to the pressure of social competition. The latter is part and parcel of the struggle for existence and depends in turn on food availability and the number of mouths to be fed. It mirrors (inversely) the standard of living prevailing at the time. In this, therefore, lies the answer to the question, What establishes the balance of numbers and prevents the progressive long-term increase or decline of populations? Fluctuations tend in practice to be checked by homeostatic processes, which can control the recruitment rate, the pressure to emigrate, and, sometimes on an immense scale, the amount of mortality resulting from stress. Only when there are long-term alterations in the environment itself will the average population levels undergo permanent change.

This sketch can give only an imperfect picture of the wide ramifications of the hypothesis. There is still one most important point to be mentioned, which is that man himself is conspicuously out of line with all the higher animals in being exposed to progressive population growth. The history of this seems perfectly clear. In many animals, including some of the mammals, fertility itself is under density-dependent control; overcrowding automatically leads to lowered, and finally suspended, recruitment. In primitive man, on the contrary, fertility was limited not through the internal effects of hormones on the rate of ovulation or on the resorption of embryos in the uterus (as in rabbits, foxes, deer, etc.) but through cultural conventions, customs, and taboos which imposed restrictions on sexual intercourse for mothers who already had a child at the breast or prescribed compulsory abortion, infanticide (especially of female infants), human sacrifices, or head-hunting expeditions. These had evolved in prehistoric man as part of a socially integrated control mechanism which kept populations nicely balanced against the carrying capacity of the habitat, exactly as in the higher animals. Then, eight or ten thousand years ago, the agricultural revolution began. Food productivity increased by leaps and bounds, and power and wealth accrued to those groups which allowed their populations to multiply, settle villages, and build towns. The old checks on population growth were insensibly for-

gotten and discarded, and none have since taken their place. We should not therefore look to nature to halt the human population explosion: it must depend on our own efforts.

### SOCIAL CHANGE

Social change is such a prevalent and often disturbing feature of contemporary life that both the specialist and the layman may be tempted to suppose that it is peculiarly modern. Certainly the extent and rate of change in the modern world are greater than in most past periods, but the static qualities of primitive cultures or archaic civilizations are easily and commonly overstated. Change, at some level and degree, is as characteristic of man's life in organized systems as is orderly persistence.

Indeed, small-scale changes may be an essential component of persistence on a larger scale. For example, given man's biological life cycle, enduring systems, such as kinship organization and government, depend upon orderly patterns of age-specific role performances. Likewise, changing patterns—on a daily, weekly, monthly, or annual cycle—provide a basic and predictable continuity to the patterns of social existence.

Paradoxically, as the rate of social change has accelerated in the real world of experience, the scientific disciplines dealing with man's actions and products have tended to emphasize orderly interdependence and static continuity. The genuine difficulties of dealing with social dynamics are in part responsible for this state of affairs. The relationship between small-scale and large-scale change and the relationship between short-term and long-term change exemplify the many analytical and factual complexities that are involved. These considerations make a formal defi-

inition of social change highly desirable, and we shall therefore attempt one here:

Social change is the significant alteration of social structures (that is, of patterns of social action and interaction), including consequences and manifestations of such structures embodied in norms (rules of conduct), values, and cultural products and symbols.

This definition encompasses small-scale change, such as the gradual development of a leadership role in a small, task-oriented group; cyclical patterns of change, such as the succession of centralization and decentralization in administrative organizations; and revolutionary change, such as the overthrow of a government. It includes short-term changes in employment rates as well as long-term changes in occupational structures; both growth and decline in membership size of social units; continuous processes such as specialization and bureaucratization; and discontinuous processes such as particular technical or social inventions.

### Social change and cultural change

The broad definition given above comprises both what is commonly identified as *social* change, which refers mainly to actual human behavior, and *cultural* change, which refers mainly to culturally meaningful symbols produced by human beings. The emphasis in this discussion will be on the interplay among the complex normative patterns of behavior that we call institutions, since it is these that provide much of the rationale for social control and human activities in general.

This emphasis cuts across conventional distinctions between the "social" and the "cultural" aspects of social systems. Cultural change, it is true, requires social actors as agents, and social change is likely to have cultural counterparts. However, changes in certain cultural subsystems—for example, language, the arts, and perhaps theological or philosophical systems—may be viewed in virtual abstraction from concrete human behavior (see, for instance, Sorokin 1937–1941). Similarly, fluctuations in the fashions of dress may be viewed as "autonomous," although it is also proper to consider such fashions as patterns of appropriate conduct in one sphere of social behavior (Kroeber 1957).

It is true that such modes of abstraction are often mere matters of convenience. For example, the steady specialization of vocabularies in language systems may be treated as a principle of autonomous evolution; it may be related to the expansion of knowledge and to role differentiation in complex social systems. However, there is an

underlying problem that should be made explicit. The degree to which cultural subsystems, such as language, may be traced to structural sources is a question of considerable theoretical importance. Similarly important is the question of the degree to which such cultural subsystems may be translated into guides for social behavior. In human societies the extent of autonomous variability among coexistent features appears to be substantial. Therefore, a multiplicity of principles relating to structural regularities and to significant alterations is necessary for the understanding of order and change.

It follows from the possibility of autonomous variability and from the initial discussion of small-scale social changes that in order to formulate principles of social change we must first of all identify the social structure to which these principles are to be applied. It is also necessary to specify the time period over which change is to be studied and to set up standards for measuring various degrees of change. Until these conditions are fulfilled, we cannot even begin to say what it is that is changing or how much it has changed. There is no singular, sovereign cause for changes in social systems or subsystems. It is true that the scientific quest for simplification has led to the identification of individual variables, such as technological innovation or population growth, that are important enough in themselves; but the result of these inquiries has been the development of special theories of change for specific classes of structures rather than any kind of master theory that embraces all types of factors.

For small-scale social structures in general—face-to-face groups, for example, or formal organizations—we can safely assume that change will originate through such familiar mechanisms as the normative requirements attached to role performances (Moore 1963, p. 50). Large-scale systems, such as whole societies, are less easily studied; but even on present knowledge we can be confident that population growth or decline and the vicissitudes of incorporating infants into the system through socialization will introduce at least some flexibilities and adjustments, if not major structural changes in a definite direction. The probability of both technical and social innovation may be inferred from a universal feature of human societies which can be called the lack of correspondence between the "ideal" and the "actual" in the realm of social values. On the whole, these innovations are likely to be directed toward both "adaptation" to the nonhuman environment, to which adjustment is never perfect,

and social control of the human population. Recognition of both of these elements can be found in the theories that we now propose to examine.

### Changing theoretical interests

The nineteenth-century predecessors of modern sociology were very preoccupied with the dynamics of social change. Although some scholars, such as Frédéric Le Play, attempted to establish canons for systematic description of contemporary social types, the attempt to trace the paths of history was a far more prevalent concern. Often the history attended to was not universal, but limited to the fairly clear antecedents of European civilization. Generally these authors attempted to find order in the succession of civilizations [see *HISTORY, article on THE PHILOSOPHY OF HISTORY*]. The most ambitious of them was probably Auguste Comte, who invented the term "sociology" and propounded a "law of the three stages"—the theological, metaphysical, and positivist—to which all civilization was supposed to conform.

**Evolutionary theories.** The directionality of change, and in particular the increasing complexity and structural differentiation of society, came to be a major tenet of evolutionary theories. Following the impact of Darwin's theories of biological evolution, Herbert Spencer, Lewis Henry Morgan, and others of lesser stature used such Darwinian notions as selective adaptation to account for both the cross-sectional diversity of societies and cultures and the supposedly sequential stages of social organization. By the end of the nineteenth century, evolutionary theory was a dominant factor in social thought, even in the work of writers who were not predominantly evolutionist in outlook. This applies to theorists as diverse as William Graham Sumner, despite his predominant concern with the relativism of all social values, and Émile Durkheim, whose life-long devotion to explaining social phenomena in terms of the balance of an interdependent system has caused him to be identified with what later became the "functionalist" approach to society.

**Marxist theory.** Even Marxism was a variant of evolutionism, particularly in its adherence to the notion of sequential stages of social organization. The Marxists tried to show how social change came about by laying great stress on the interaction of technology with social organization. Indeed, Marxist thought in its crudest form shared with most evolutionary theory a belief that one stage of social organization succeeded another through the operation of forces that were as impersonal as they were inevitable. Marx himself,

however, took fairly full account of the purposive character of social action; he did not rely solely on his theory of revolutionary change. Moreover, his theory was a dynamic one, although it underplayed the independent role of ideas and values; thus his intellectual heirs were never caught up in the extremes of static "functionalism" that later became a dominant theme in anthropological and sociological theory.

**Functionalist theory.** Functionalism is the attempt to explain social phenomena by other social phenomena that are contemporary or quasi-simultaneous. In this respect, it rejects the "quest for origins." Some of its proponents (e.g., Durkheim, Radcliffe-Brown, Malinowski), in eschewing explanation in genetic terms, also tended to suppress all queries about the actual dynamics of change. For them, the demonstration of interdependence between different elements of social structure came to mean the search for self-equilibrating mechanisms in society.

The recent revival of interest in dynamics owes something to all of these precedents. From functionalism, contemporary theory derives not only notions of systemic linkages which *may* be sequential, but also, through the concept of "dysfunction," some notions of tension and incipient change. However, the renewal of concern with analysis of social change probably owes more to the undeniable facts of contemporary life and particularly to the social scientists' resultant involvement in studies of modernization. Although functional systems models have served rather well as predictors of eventual expected changes in elements of social structure held to be related to economic development, the unconfirmed assumption that all fully modern societies have essentially the same kind of social structure can only lead to an unwarranted sociological determinism. In any event, this mode of analysis has produced a kind of "comparative statics," offering a before-and-after view curiously discordant with older evolutionary theories; for the functionalists' standard treatment of modernization dwells on pre-existing heterogeneity that becomes in due course a homogeneity. Nevertheless, functionalist studies of modernization have at least the merit of demonstrating a serious but fortunately remediable weakness in the analytical models employed, namely, that before-and-after comparison diverts attention from the mechanisms of change and entirely suppresses inquiries about actual sequences and timetables.

**Alternative models of societies.** Any theory that views society as a "functional equilibrium system" has the advantage of telling us that certain vari-

ables need to be correlated with certain other variables if the theory is to prove its worth. In any case, some such model of society, whether implicit or explicit, underlies most of the better attested propositions about social action and social structure in contemporary American sociology; indeed, these propositions are American sociology to a great extent, and their influence on other branches of social science is already profound. In spite of the objections already brought against functionalist theory, its prevalence is not necessarily to be deplored. Functionalism, in the hands of a sophisticated theorist, does not preclude attention to deviance, nor does it prejudge the issues of stability and continuity in social change theory. Indeed, to specify "the functional prerequisites of a society" (Aberle et al. 1950) is to adopt an implicitly evolutionary position, for the notion of functional prerequisites not only gives rise to high-level generalizations about the features common to all societies but also, by applying the test of survival, explains the failure of past society by their want of one or more "operating characteristics." The sophisticated functionalist, therefore, views society as a "tension-management system," thus making order itself problematic; he welcomes empirical study of the uncertainties and conflicts that arise in society from disparities between the ideal and the actual.

One of the few viable alternatives to functionalism that have been offered is the "conflict model" of society (Dahrendorf 1957). However, this does not appear to be a comprehensive construction, but only a change of emphasis to discordant elements and interests as a counterpoise to models that stress social integration. Moreover, the tension-management model, as described above, already identifies structural tension points as probable sites of change.

### Problems of detection and measurement

Change takes place in *time*, and time for observation is limited, especially for the single investigator. One method that has been devised for coping with this problem is the "panel study" [see *PANEL STUDIES*]. This is a method that attempts, over relatively brief periods, to record changes in individual attitude and behavior while they are in process. For longer periods, there would appear to be no substitute for historical evidence. Here the social scientist commonly turns to the professional historian; but the historian's interests do not often coincide with those of the sociologist, and it is not surprising if data that would help to answer sociological questions are either passed over or dealt

with only briefly in works of history. Moreover, historians have rarely made use of quantitative techniques of data reporting, and the sociologist interested in constructing actual rates of change may have to do his own history. Finally, there is the undeniable fact that much of the past is irretrievably lost to human knowledge. The assembling of social statistics is very recent in man's history and still very incompletely practiced [see *CENSUS; GOVERNMENT STATISTICS; LABOR FORCE, article on DEFINITIONS AND MEASUREMENT; VITAL STATISTICS*].

**The problem of magnitude.** It was earlier noted that the question "What is changing?" is primary. The identification of elements or constructs for observation and analysis is a theoretical matter. Opinions may properly differ as to what constitutes a "significant" change; there is no legitimate scientific basis for denying social scientists their interest in the tiny alterations that occur in small groups or in the day-to-day developments of a political campaign. Questions of magnitude, however, cannot be avoided if we are to talk about social change in general. How much of a change is to be taken as "significant" and by what criteria of significance?

If the system constructs explicitly or implicitly employed by some functionalists were to be taken seriously, this problem could be solved simply by the strict dichotomization of change as "trivial" or "tragic" (Moore 1963, pp. 20, 70). In its extreme form, the assumption that all parts of a social system are completely interdependent results in the dilemma that change must be viewed either as constituting only variations on a theme within tolerable limits of persistent order ("trivial") or as so altering an essential social component as to have serious repercussions throughout the entire system ("tragic"). However, the problem is not that simple. The structural looseness of social systems is not only evident but empirically verifiable; it is therefore possible that some small-scale changes alter social systems by cumulative degrees. How much change, in what, has what predictable consequences for which specifiable classes of social phenomena?

**A demographic example.** Some examples from demographic behavior may help to clarify the issue. Let us suppose that mortality rates are relatively low and temporally stable and relatively uniform in terms of such standard social categories as residence, ethnicity, occupation, and income. Let us also suppose that birth rates are relatively low and that the modal number of children per family is again relatively uniform across social categories.

Now let us suppose a fairly rapid rise in birth rates, which in familial terms means an increase in the modal number of children from two to three. Such a change will have only minor consequences for the structure of the family, the consequences being limited to the nuances of generational and sibling relations. But the *aggregative* effect of this change on the economy, the density of population, the demand for schools and teachers, and so on, will be major; indeed, if we make allowances for the simplified nature of this example, it can serve as a description of the "baby boom" following World War II. Now let us alter the assumption of the independence of family size with respect to various social categories. Let us suppose, rather, that over the course of a few decades the average size of family changes from a distribution inversely correlated with measures of socioeconomic status to a strongly positive correlation. Children would then become another symbol of affluence, but the effects of the change would be more complex. For example, with regard to mobility opportunities, it would appear that the relative smallness of poor families would favor a more equitable distribution of meager resources for current support and continuing education. Yet the advantages accruing to the children of well-to-do-families would probably persist; indeed, to the degree that inheritance of status continues to operate, the saturation of the upper ranks would preclude substantial upward mobility on the part of children of humble origin. In fact, if the fertility differentials were sharp, only a changed status distribution resembling an inverted pyramid could avoid substantial downward mobility among the well-born.

These partially hypothetical illustrations of demographic trends underscore the importance of looking for consequences of any kind, whether they are direct or indirect, small-scale or large-scale.

**Problems of identification and observation.** The ease with which social change can be identified or observed depends on at least four variables, all of which characterize the dynamic pattern of change. These variables are scale, brevity, repetition, and mensuration.

**Scale.** "Scale" is a somewhat ambiguous term, which may refer to the size or comprehensiveness of the system affected—for example, the political structure of a whole society as compared with a local custom relating to courtship—or to the degree of alteration in the system. As magnitude in the latter sense implies at least crude measurement, the "scale" variable is most appropriately reserved to refer to the comprehensiveness of the system involved. These two variables—the size of the sys-

tem and the degree of alteration—are of course likely to be positively correlated. However, the correlation is not perfect; small changes can occur in inclusive systems and large changes in subsystems.

**Brevity.** Changes that are completed in a relatively short time are likely to be more observable than those that take place over a longer time, even if the latter eventually become substantial in magnitude. Long-term cycles which occur on a large scale may be detected retrospectively; however, they will probably go unnoticed if they are on a small scale and involve only small degrees of variation.

**Repetition.** Relatively brief changes, even if of small magnitude, have a greater chance of being observed if they are repeated frequently—in a cyclical pattern, for example. Repetition, in fact, greatly facilitates explanation and prediction, in that chance antecedents may be more readily distinguished from common and efficacious ones. In this respect, the repetition need not be confined to a single social unit, provided that there is enough similarity among units to allow for comparison. Thus some of the social changes related to industrialization are unique and discontinuous with respect to past trends in areas undergoing modernization, but they are sufficiently repetitive from one society to another (time for these purposes being only an incidental variable) to permit the formulation of general principles.

**Mensuration.** For large-scale transformations in social systems, such as political revolutions or rapid industrialization, the quest for quantities may seem unnecessarily laborious. Yet even here numerical indicators are likely to be useful for comparing cases, and they are particularly necessary if one is going to speak at all precisely about rates of change. In the case of less dramatic social transformations, the perception of change may not be uniform, and reliable measurement may therefore be the only way of settling the issue, as well as of finding at least partial explanation for clearly demonstrated changes. For example, is mental illness increasing in the United States and other modernized societies? If so, by what standardized criteria of identification and diagnosis can the increase be demonstrated? If it is demonstrable, how can cross-sectional differences in rates—for example, by age or income—be converted hypothetically into temporal trends, still using these same indicators? Failure to exercise both quantitative ingenuity and great methodological caution is likely to produce only a spurious explanation for a fictitious trend; such academic exercises unfortunately have been too common.

**Demonstration of causal processes.** It is very rare, in studies of social change, that we come across a classically neat demonstration of a singular cause, producing a singular effect, under finitely specifiable and repeatable conditions. This is partly because of the difficulty or impossibility of fully controlled social experimentation. A further difficulty is the inadequacy of the currently available conceptual and observational tools. Usually the analyst deals with statistical probability distributions and attempts to explain various "dependent variables" so characterized in terms of "independent variables" having the same uncertainties. Statistical techniques have been developed for dealing with these crudities, and others are likely to be invented [see CROSS-SECTION ANALYSIS].

Sequential analysis, however, involves additional problems, for it takes into account not only the degree to which the outcome is determined by one or another measurable antecedent but also the important question of the temporal order of critical variables. Smelser (1962, pp. 12-21) has borrowed from economics the term "value-added process" to refer to this type of logical scheme for organizing the determinant variables. This methodological principle offers the analyst some prospect of moving from the demonstration of necessary conditions to the understanding of sufficient conditions for social change, under favorable circumstances of observation and measurement. The notion of "value-added process" resembles various "stage" theories of change, although stages often represent arbitrarily imposed discontinuities in cumulative trends and thus understate the interaction of variables in the process of transformation.

One of the more complex forms of evolutionary change has been identified by Arnold Feldman and Wilbert E. Moore (1960) as cumulative, retroactive evolution. This term refers to the process by which later "stages" have a continuing or delayed effect on seemingly earlier ones. The mathematical conception of "stochastic processes" is a more accurate designation for this process than the concept of "stages." However, the delineation of stages is a useful mode of characterizing sequences that exhibit fairly clear breaks in rates of change and "emergences" that fundamentally alter the properties of social systems.

### The directions of change

In accordance with the position that only "special" theories of social change are appropriate to the diversity of social phenomena, the varieties of directionality in change will each be illustrated empirically. Although many of these have been

offered in the past as master principles of social dynamics, the eclectic view here espoused has clear advantages in terms of factual confirmation, even if it thereby loses in simplicity and level of generalization.

**Evolutionism and relativism.** The principal mistake of the evolutionary theorists of the latter half of the nineteenth century was overgeneralization. The rectilinear theories of human evolution either took too little account of diversity or explained it improperly. Although Spencer's concept of the "superorganic" offered promise of recognition that human societies might show some portion of the diversity of plant and animal species, he was too bound by the idea of the biological unity of mankind to exploit his fundamental idea. Later theorists went to the opposite extreme by ignoring biological factors and emphasizing sheer unexplained diversity. This extreme relativistic view was no more acceptable than the evolutionists' idea of lining up all of the world's cultures in rank order, with the presumably "simpler" social organization representing a kind of unexplained primitive survival.

**Fluctuations and cycles.** In the analysis of social dynamics, the counterpart of the recognition of simple cross-sectional diversity has been the identification of "fluctuations," that is, variations through time which show no clearly repetitive or cumulative pattern. Fluctuations do indeed occur; for example, consider the chance variability in reproduction and the uncertainties of the intersection of hereditary and environmental factors in personality formation. In fact, the vicissitudes of matching recruits with the normative requirements of enduring positions insure some fluctuations in the exact behavioral counterparts of established structures (Sorokin 1937-1941, vol. 4; compare Moore 1963, pp. 66-68).

As compared to fluctuations, cycles involve more determinate directionality. A simple pendulum swing between extremes (e.g., prosperity and depression, liberalism and conservatism, innovation and accommodation) represents the simplest cyclical pattern. The delineation of multistage cycles is likely to rest on tenuous analogies (e.g., the "life cycles" of civilizations) or to require somewhat arbitrary breaks in variables that on inspection show rather orderly trends.

**The self-equilibrating model.** The notion of "self-equilibrating mechanisms" in functional systems is more readily understood in terms of trendless cycles than it is in terms of a static continuity which is only occasionally disrupted by external disturbances. For example, there is a tendency in

administrative organizations for "indulgent" departures from strict compliance with the rules to grow more extreme, until reversed by a renewed insistence on approximate compliance. This might be characterized as the "cycle of sin and penance." Yet the notion of "self-equilibration" often implies that trends are reversed because of side effects of actions taken by the participants. This mechanistic assumption is not always warranted; the question as to whether the direction of change is deliberate is always a proper one.

A further point about cyclical change may be derived from the example of a small-scale repetitive pattern just used. Cycles may be superimposed on an underlying, cumulative trend. Thus the "return to the rules" in an administrative organization is unlikely to be complete, and through successive repetitions of the sequence there is likely to result a long-term modification of the norms themselves. On a larger scale, the alternation of relatively high and relatively depressed economic indicators in complex economies may represent essentially short-term variations that are consistent with long-term growth as indicated by per capita income or similar measures of economic development.

**Progress as an aspect of growth.** The evolutionary theorists of the nineteenth century were also naive in that they exaggerated the cumulative nature of change and comfortably equated change with "progress." However, to some extent the cumulation of which they spoke was real—a point missed by all their relativistic detractors. For various sectors of any social system, and even for entire systems, there is evidence of steady or even accelerating growth over long periods of time. For instance, the growth in the number of rules in continuing organizations is certainly not at a steady rate if very frequent temporal comparisons are made; however, it is probably very steady over somewhat longer intervals. Likewise, the growth in total human population has been variable over considerably longer periods, and yet cumulative over the entire span of man's earthly tenure. Rates of technical innovation are variable according to time and place, although commonly on a cumulative base. If the invention rate is the unit of observation, its trends may appear nearly cyclical over extensive periods of human history. On the other hand, if the sum total of useful knowledge is taken as the basis of observation, the short-term variations in the rate of addition to stock are likely to appear as very minor fluctuations in the long-term accumulation of reliable knowledge. This is because the growth of knowledge takes place at an

*exponential* rate: the more there is, the faster it increases.

**Measurement of trends.** Conclusions about both the rate and the direction of social change are much affected by the choice of time intervals of observation, including the span between the initial and terminal observations. Constant surveillance of ongoing processes is rare outside the laboratory and nearly impossible for long-range changes. Frequent recording of observations tends to pick up cyclical patterns and essentially meaningless fluctuations. Infrequent recording loses such information and points instead to more enduring trends. This is not to argue for less information, as infrequent observations are subject to grave risks of sampling error in the peculiarities of the observational situation. Skilled analysis can distinguish mere fluctuations, short-term trends, and long-term trends from a "continuous" series. The fact is, however, that in the retrospective analysis of long-term changes the analyst is more likely to detect a "fundamental" trend; thus the finer processes of transformation may be lost to view.

**Mortality and fertility trends.** A further example of great substantive importance may serve to underscore the problems of sorting out short-term and long-term trends. Contemporary evidence and all reasonable inferences from available historical materials indicate fairly wide short-term fluctuations in death and birth rates. But they also indicate two clear longer-term patterns. Over the very long term, human population growth has followed the cumulative, accelerating (*exponential*) pattern. Examined in somewhat more detail, the shorter-term patterns exhibit greater variability in mortality than in fertility in "nonmodern" societies and greater variability in fertility in modern industrialized societies.

Furthermore, the steady decline in mortality, followed, after an interval, by a steady decline in fertility, are trends uniformly accompanying economic development. The trends represent a dynamic pattern that is repetitive, although the pattern seems to operate only once in each economic unit.

This example can be pushed still further with respect to the direction of change. The variation in mortality in "premodern" societies appears to be rather irregular, as it is determined by such "chance" factors as climate and harvests, political vicissitudes, and infectious diseases. On the other hand, the variation of fertility rates in "modernized" countries seems to approximate a cyclical pattern. In societies where contraception is practiced, birth rates are likely to be correlated with *current* economic indicators [see FERTILITY CONTROL].

However, there is more than a slight suggestion that fertility functions not only as a dependent variable but also as an independent variable. Prosperous conditions result in exceptionally high fertility. As these birth cohorts reach maturity they tend to oversupply the prevailing labor demand, which serves to increase unemployment and other unfavorable economic indicators. These deteriorating economic conditions in turn result in small birth cohorts. Note that if this reasoning has further empirical validation (and it fits rather well the fertility behavior of Western countries for several decades following the 1930s) we shall have an example of a "self-disequilibrating" system. The cycles remain "off-phase" because of the intrinsic lag entailed in bringing infants to the age of labor-force participation.

**Cumulative trends.** The ways in which cumulative trends display themselves are numerous. To simple, additive (rectilinear) change and accelerating (exponential) growth should be added one form or another of "logistic" trend. A slow increase accelerates because of an increasing base for combinations to take place, but then it "dampens off" as severely limiting conditions are encountered. The size of organizations and even of entire populations often display this pattern. However, it must be remembered that the parameters or restrictive boundaries are themselves subject to change—for example, by technological or organizational innovation. Moreover, the lower limits, as well as the upper, may serve as restrictive boundaries. For example, the decline of mortality is commonly described as a "reverse J-curve," meaning that early and easy improvements in health conditions are followed by more and more difficult life-saving measures until the limits of biological survival are approached.

### Structural differentiation and social change

The directionality of change can be represented in terms of measures of size, incidence, or occurrence. Moreover, certain *processes* of change may be found to have a reliable and enduring direction. Most notable of these in the theoretical literature is the presumably universal tendency toward specialization or structural differentiation. But the question of why this should be so is commonly left unanswered, the process being taken as given. Durkheim (1893) and others sought a demographic explanation: growing numbers lead to more complex social arrangements, including positional and role differentiation. Extensive evidence does point to a high, but by no means perfect, correlation between size and specialization; however, the reasons

for this correlation are left for the most part unexplained.

In Darwinian evolutionary theory, structural differentiation derives from selective adaptation of organisms to their environment. Since environments differ both cross-sectionally and temporally, the idea of selective adaptation provides a way of accounting both for the observed diversity in structural forms and for continuing change. It is surprising that so little use has been made of this conceptual scheme in the theory of social systems, where it appears equally applicable. In this scheme, population or membership size would serve as a basis for increased potential variability, and differentiation internal to the system would be one mode of adaptation of the entire system to its environmental setting. Criteria of efficiency in optimizing goal achievement—criteria which may be overt and purposive in complex social systems—would then be particular forms of adaptation.

Specialization is not, of course, an absolutely sovereign and irreversible dynamic process. Occasionally, its dangers to systemic cohesion may lead to renewed emphasis on unity and commonality of participating units. However, the probability of continuing specialization in enduring social systems is high. The cumulative growth of reliable knowledge and technique abets the requirement of differentiated competence.

Structural differentiation does imperil systemic cohesion, as just indicated. Mere interdependence, as Durkheim (1893) demonstrated, does not insure "solidarity." Solidarity, or systemic cohesion, also requires an effective system of norms, which in turn will be justified or rationalized by common values. The *mechanisms* of effecting coordination are chiefly two: exchange, whether through relatively impersonal monetary markets or other forms of complementary reciprocities; and administrative authority, a mode of allocating duties and insuring compliance by the exercise of institutionalized power. These mechanisms are not of course mutually exclusive; for example, subordination to authority may be contractual.

A supplementary note on directionality is appropriate. Any of the forms of change we have identified may be associated with ideas of "progress," which is simply change in an evaluatively approved direction. It is of course not itself a scientific principle, but as an item of belief it is possibly a relevant social datum. Progress may be viewed by social participants as the continuation of cumulative growth, as the dampening of cyclical oscillations and return to a steady state, or even the return to a past state which is evaluated as superior

(the concept of "primitivism"). But since social action is partly purposive, the direction of change may well reflect the *desired* direction of change. Thus ideas of progress may be important elements in accounting for observed dynamics.

### The problem of discontinuities

Change is most readily perceived as "orderly" when measured trends display a uniform direction or rate or when cycles are repeated often enough to confirm their character. Even lawful acceleration (Moore 1964) such as the exponential curve, which makes the rate of growth proportional to the extent of the relevant universe at any time, displays an underlying order. From a theoretical point of view, such orderly change clearly requires persistence or repetition in the ambient conditions. From a practical or procedural point of view, orderly change provides sufficient time for the identification of causes and the refinement of observation and measurement.

Analytical difficulties multiply when change is in a significant sense and degree "discontinuous." For example, extremely rapid change, even if its antecedents are clear, may in turn alter the fundamental structure of the underlying change-producing conditions. The "successor system" which emerges can be described as "qualitatively" different. This does not mean that measurement is no longer possible or appropriate; it does mean that new variables and parameters must be taken into account.

Two illustrations from the contemporary world are relevant here. In retrospect, the discovery of nuclear fission and fusion may be viewed simply as an evolutionary step in the pattern of multiplying power utilization (White 1949). But the *implications* of that power for international politics, space travel, and economic production have introduced new dimensions into the potentialities for further change. At the more strictly social level, the extremely rapid spread of the doctrine of economic development has substantially reduced the cultural insularity of tribal societies and archaic agrarian civilizations and thus has increased the theoretical and practical utility of viewing the entire world as a single system.

Closely related to such "emergent" phenomena as the social and political effects of atomic power is another class of events that we propose to call "threshold" phenomena. By this we mean that the cumulative and interactive effect of changes that are analytically separable may result in unprecedented transformation. Thus, although there is no precedent for a *rapid* decline of birth rates in the

course of economic development, several antecedent conditions for a sharp break with the past may be noted. They include the potentiality and actuality of mortality reductions at a much more rapid rate than in the oldest industrial countries; a nearly universal political adherence to rapid economic development, coupled with growing recognition that economic programs are imperiled by extremely fast population growth; and a steadily changing "technology of contraception" that may greatly increase its economic and aesthetic (and perhaps even religious) acceptability.

The concept of the threshold emphasizes sequential rather than factorial analysis of causation. Like Smelser's use of the "value added" concept (Smelser 1962), it represents an attempt to move from necessary to sufficient conditions in the prediction of change, including alterations in direction, rate, or subsequent characteristics of the social system which merit the designation "discontinuous."

**Reversal of trends.** Trends may reverse as well as cumulate to new levels. The upswing in birth rates among industrially advanced countries following World War II illustrates completion of a process of change, after which the number of children per family began to be determined by previously unimportant factors. The historic decline in fertility owed something to marriage rates and ages, but chiefly reflected an extending pattern of contraception. As indicated by the then standard inverse relationship between fertility and socioeconomic status, the leading practitioners of contraception were those families which could best afford children. But in the course of time the attitudes and techniques favorable to family limitation became less and less the exclusive possession of upper-class and middle-class families. Apparently, it was chiefly education, among the various criteria of status, that had the greatest influence on family limitation, and it is also noteworthy that it is education that has exhibited the greatest equality of distribution. When a third or fourth child was no longer putative evidence of ignorance and error, but rather might be interpreted as a choice of family size, birth rates began to take on the characteristic trends and distributions of the markets for "consumer durables."

**Persistence of traditional structures.** Similarly, economic modernization is never "complete." Its initial, discontinuous impact on traditionally organized societies may be followed by partial restoration of structures and forms which were never completely destroyed. For example, the weakening of extended kinship systems as a consequence of

geographic and social mobility may be followed by partially restored, though discretionary, communication and reciprocities among kinsmen. Likewise, stable exchange or employment relations are likely to lose some of their nominal austerity and impersonality. Note that this is not to say that the *status quo ante* is fully restored or that nothing significant has changed, but only that the conception of an unusually disruptive "transitional period" has some merit.

**Revolution as discontinuous change.** Fundamental "social revolutions" represent an extreme form of discontinuous change. Although social scientists have been at some pains to emphasize the partial restoration that occurs even after major revolutions, by definition revolutions involve fundamental changes in institutional structure and distribution of power. Polarization (for instance, of social classes of interest groups) is of course one antecedent of revolutionary change; however, polarization in turn requires explanation. Under the conditions of political centralization, substantial urban agglomeration, and fairly effective communication, polarization is likely to occur when there is an absolute or relative decline in economic well-being or political rights among those already largely excluded from positions of affluence and power. The decline, of course, must be fairly severe, sharply differential in its impact, and numerically extensive. Although this form of change is implicitly quantifiable, very little quantitative analysis of the antecedents of revolution has been attempted. Polarization, for example, is typical in the modernized sector of societies which are in early stages of industrialization. Yet in the majority of historical cases that sector has been too small to provide a clear revolutionary potential, and as it has expanded it has also reduced its polarity. How extensive and rapid must "early" modernization be in order for it to produce social revolution? The apparently faster change in aspirations than in the means for their fulfillment in contemporary developing areas invites the speculation that the incidence of revolutions may increase in the future. Refinement of that speculation into a responsible probability distribution awaits the collection of comparative data, both cross-sectional and temporal.

### Forecasting the future

Theories of social change have little claim to scientific merit unless they are formulated as verifiable predictive propositions concerning the relations among variables. However, in the "real world"

the interaction of factors is very complex, and it may be difficult to replicate or control the conditions under which the causal variables are sequentially related. Thus, generally speaking, small-scale and short-term changes are easier to predict than their opposites. Science cannot predict the unique event with absolute reliability; it can only assign probabilities to individual occurrences in a class of events. In this respect, the task of the historian, whose data are in principle "all in," is substantially easier than that of the sociological prophet, who may not foresee crucial intervening events or even be able to assign correct values to available information.

Although the precise shape of the future is hidden by a haze, there are several bases for at least rough and partial prediction. The first of these is the simple *persistence* of past and present conditions. Fortunately, for much of social conduct we can make this assumption; otherwise we would not know how to act or what to expect from day to day. Customs, organizations, and values may be expected to survive the pressures of other changes over long periods of time. For example, we may predict with fair confidence that the United States will continue to have a constitutional government; although it may experience some shifts in political influence and even in the relative powers of the executive, the legislature, and the judiciary, it is not likely to become a one-party regime or adopt a strictly executive mode of government. Moreover, the expansion of the size and functions of government does not lead us to expect the end of pluralism or any substantial reduction in the large measures of individual and private-group choice, decision, and competition which are characteristic of the "open society." Some American traits, such as pragmatism in attacking problems and a kind of rational, secular view of most social institutions, look like hardy survivors from the past which will continue into the future.

A second basis for prediction is to be found in the *continuation of orderly trends*. In addition to our earlier discussion, some other probable trends may be noted. In the United States, the rate of urbanization and suburbanization has been increasing, but changes in the rate have been fairly orderly over three decades. The average age of marriage has been decreasing, but at a slowing rate. The proportion of secondary school graduates has been increasing, as has the proportion going on to college. Women are entering the labor force at a gradually rising rate, particularly at ages over 45 and under 60. The amount of private saving increases as the

economy grows and income increases, but the proportion of money saved remains remarkably constant. Some of these trends have a decade or two of history behind them and some much longer periods. With the extension and improvement of social accounting, the examination of trends may become an increasingly important basis for forecasting.

Some destinations are known because the route has been traveled before. In addition to small-scale repetitive patterns, the contemporary world offers examples of large-scale recapitulated experience. In the course of economic modernization, precise replication of "Western" rates and sequences of change will not occur often. However, on the basis of what is known about "Western" experience we can go rather far in predicting the course of social change in major parts of the social organization and value systems of societies which are now seeking to become part of the modern world.

Another component of forecasting is the great and growing importance of planning, which is of special significance in industrial countries and those attempting to become industrialized. A remarkable amount of energy and other scarce resources is spent on forecasting autonomous trends and calculating intermediate adaptations and on deliberately implementing future goals. Although accidental and "mindless" change still occurs, social change is increasingly both organized and institutionalized. The future is partially predictable because it will resemble in part what it is now intended to be.

## SOCIAL COHESION

See COHESION, SOCIAL.

## SOCIAL CONTRACT

"The social contract" is the term applied, by a long-standing consensus among students of politics, to the political theories of the most famous and influential thinkers of the period reaching from the mid-seventeenth century to the mid-eighteenth century: Thomas Hobbes, 1588-1679; John Locke, 1632-1704; and Jean Jacques Rousseau, 1712-1778. Scholarly tradition has associated the three because of their alleged common insistence that society originated in a contract, compact, or agreement, explicit or tacit, to which each individual concerned consented and, so, removed himself from the "state of nature" and helped set in motion a regime of government under laws, of impartially administered justice, and of civic morality. Recent scholarship, however, has tended to fix attention on other and perhaps more significant reasons for thinking of the "contractarians" as a school, or movement.

## The social contract school

Hobbes, Locke, and Rousseau were all concerned with emphasizing the contract as an explanation of the *nature* rather than of the *origin* of society—that is, to get across the idea that whatever the origin of society, the relation between the individual members of society and their obligation to obey society's government and laws are fundamentally contractual even in the absence of a formal agreement. Put otherwise, none of the three committed himself unambiguously to the "historicity" of a freely negotiated contract among men in the act of emerging from a state of nature. Hobbes, for example, was willing for the subscribers to his "contract" to be bludgeoned into participation by any strong man capable of forcing their compliance. Locke was willing for the participants to be nursed into compliance by a "godlike" king. Rousseau placed great stress on the role of a "founder," or legislator, in midwifing the contract into existence over a long period of time.

The influence of Machiavelli. All three, if not avowed pupils of Niccolò Machiavelli (who was in disrepute during most of the period in question), at least wrote as if they had been profoundly influenced by Machiavelli. Each was less committed to the contract as explaining the origin or even the nature of society than to certain other ideas which Machiavelli first enunciated: (1) Man and society

are not coeval (as earlier thinkers had asserted); rather, society, like government, law, justice, and morality, is a human artifact, which man is free to alter or dispose of as he sees fit. (2) "Natural" man—that is, man as he must have been prior to the founding of society—is not (as the earlier tradition had held) social or political "by nature"; rather, man first participates in society and continues to participate in it out of one form or another of "fear" or "terror" at the thought of the dire things that will happen to him if he does not participate; man "becomes" social or political only by virtue of the qualities that society superimposes upon his nature through a long process of habituation (man, as Machiavelli put it, is neither good nor bad by nature, but merely malleable). (3) The proper concern of political philosophy is not man's "perfection" or "end"—not, in Rousseau's phrase, "men as they might be"—but men as they are; political philosophy must not fritter away its energies on what Machiavelli called imaginary utopias but must treat of the building of actual societies capable of ministering to the needs and wants of men as we actually know them. (4) There exists no natural or divine law that imposes on men anywhere and everywhere "perfect" duties toward one another and toward society itself, of which their "rights" are derivative. Here, indeed, the contractarians went further than Machiavelli, who had not concerned himself with rights at all, and held that the one firm statement we can make about "rights" is that each man is born with a "right" to "preserve himself" and to choose freely the "means" to his self-preservation.

In summary: Their common dedication to these ideas—all "revolutionary" vis-à-vis the "great tradition" and all rooted in Machiavelli—far more than their use of a "social contract," binds Hobbes, Locke, and Rousseau together into a school. [See MACHIAVELLI.] Viewed in this context and irrespective of whether or not they wrote under Machiavelli's direct influence, the three together constitute a "bridge," moored at one end on Machiavelli, that stretches from the political philosophy of the "great tradition" of the West to the predominant political teachings of the present day. Each, in his own way, contributed to the accomplishment of Machiavelli's avowed purpose: to emancipate mankind from the "bad" tradition inherited from Plato, Aristotle, Cicero, Augustine, and Aquinas.

The right of self-preservation. Hobbes, Locke, and Rousseau built their "models" of political society on the "right of self-preservation" and thereby gave to the word "right" a new and revolutionary meaning. The great tradition, insofar as it had

spoken of "rights" at all (both natural and divine law had emphasized duties, not rights), had conceived of every right as encrusted in a complex, or system, of duties and rights. Its rights had been, therefore, "correlative" to duties, in the twofold sense that, first, a man divested himself of his rights if he failed to perform their correlative duties and, second, that "my" right had been understood as carrying with it a correlative duty on "your" part to respect that right. Not so with the right of self-preservation, which the contract theorists attributed to every man at birth; it carried with it no correlative duties, nor were a man's fellows under any obligation to permit him to exercise it.

One might say that the contract theorists divested the word "right" of any moral connotations whatever: Exercising my right of self-preservation, I enter society, or remain in it, because it seems, from a strictly "selfish" point of view, the best "means" at my disposal for preserving my life (or, in Locke's phrase, my "life, liberty, and estate") and not because of any duty toward my fellow men. [See DUTY.]

**Challenges and contributions.** The four major burdens upon each contract theorist, their handling of which marks the significant differences between them qua contract theorists, were (a) to present a picture of natural, "presocial" man (for the purpose of which they used the device of the "state of nature"), which would render plausible the idea of his entering the "state of society" at all; (b) to show that such and such a "state of society," characterized by such and such a "contract," is a transaction that a rational man, armed only with his right of self-preservation, would choose as the best available means for preserving himself; (c) to account for the obligation on the part of the participants in the contract to keep the "promise" they have allegedly made; and (d) to show why persons born and reared in society subsequent to the negotiation of the contract should be understood to have "consented" to the contract's terms.

None of the three great contract theorists was able, in the judgment of subsequent scholarship, to meet these four challenges successfully, which perhaps explains the fact that the contract device disappeared from political philosophy soon after Rousseau.

However, other ideas that derive either from the school as a whole or from one or more of its members have deeply influenced both political events and political thought throughout the intervening period: first, the notion that no society, government, law, or rule of "morality" is legitimate unless

it rests, directly or indirectly, on the consent of the individuals concerned, though not necessarily consent to a contract; second, that the proper concern of political science is the political behavior of individuals and groups of individuals; third, that societies, governments, laws, and notions of right and wrong or of just and unjust are to be judged by the recognition and protection they provide for "inalienable" individual rights, conceived as inherent in all human beings in all times and places; fourth, that one of these rights is the right to live under a democratic government, that is, government subject to popular control understood as involving, in the absence of unanimity, control by the majority; and fifth, that, in the sense that should be decisive for politics, all men are born equal and that one major purpose of government, therefore, should be to promote equality.

### Antecedents of the social contract

The Hobbesian contract marked a turning point—and in some respects a genuine innovation—in the history of political philosophy. But Hobbes possessed a vast knowledge both of history and of traditional political philosophy, and he, along with Locke and Rousseau, is sometimes said to have been indebted for all or some of his basic ideas to one or another of several sources.

**The Greek "conventionalists."** We know, chiefly from passing references in the writings of Plato and Aristotle, that classical political philosophy itself arose in opposition to a long-dominant school of political thought in which the idea of convention played a role comparable to that of the compact in Hobbes. The contentions of that school were that the Greek city-state, the only form of society the Greeks knew, was a product not of nature but of the kind of tacit, constantly evolving, mutual understandings by which, for example, we today think of languages as originating and developing; that this is equally true of government, of law, and of notions of good and bad and just and unjust; and that it is equally true also of the citizens' habit of obeying the laws of his city.

Among the names of the pre-Socratic conventionalists (of whose utterances we possess only fragments), the most prominent is that of Heraclitus, 575–480 B.C., but some of Plato's and Aristotle's archenemies, the Sophists, defended the conventionalist position. We may say of it, in general, that it is very close to the modern social contract theories in its denial, explicit or tacit, of what were to become the central propositions of classical political philosophy but very remote from those theories in its assertions; conventions, as understood

by the conventionalists, carried with them no obligation and certainly not a contractual obligation. But there is this common ground between the conventionalists and the contractarians: they agree that society, justice, and law can have no superhuman or transcendent source and are therefore "man-made."

*Glaucon's statement.* In the beginning, says Glaucon in Book II of Plato's *Republic*, each man thought it good to inflict injustice upon others and had to suffer injustice at the hands of others; all men behaved accordingly. In due course, however, men came to consider the resulting state of affairs intolerable and proceeded to agree to covenants and laws that obliged them to behave less rapaciously. Such, Glaucon continues, is the origin of justice, which is merely what the agreed-upon laws command, and men accept those laws because it is in their interest to do so. Glaucon, we notice, makes the shift from "convention" to "covenant"; he stresses self-interest as the central motivation in political behavior; and he posits (since, on his showing, there must have been a first covenant) an epoch in the past when men were "presocial," "prelegal," and "premoral." All three of these ideas, which were at most present by remote implication in the conventionalists as such, clearly do anticipate the position of the later contract philosophers. (Of course, Plato's purpose in presenting Glaucon's statement is to discredit the position.)

*The Biblical covenants.* The Old Testament recounts numerous instances of "covenants" between Jehovah and particular individuals (e.g., Abraham) and between Jehovah and the people of Israel. Although they perhaps helped to familiarize subsequent generations with the idea of binding agreements or "contracts," they may be dismissed out of hand as sources for the modern contractarians. They were, in the nature of the case, agreements between Jehovah and an already existing society; the "law" to which they subjected the people of that society pre-existed it and was allegedly not of human origin. (But cf. Gough 1936.)

*The medieval social contractarians.* History records numerous examples (the earliest of which probably was the Acts of the Fourth Council of Toledo in 633) of contracts between kings and peoples which limited the power of the king by declaring his subjects' allegiance dependent upon his recognizing certain of their rights, upon his making new laws only after consultation with the wise men of the realm and with their consent, and upon his promising, often in a coronation oath, to rule justly and in accordance with divine law and

the laws of the realm. Since these contracts did not *create* societies (one of the parties to the contracts was a people that already existed) and since they presupposed justice, law, and morality as goods of transcendent origin rather than human artifacts, their relevance here consists solely in the fact that they did keep alive the idea of contracts as a possible source of political obligation. So, too, with the vast body of medieval literature, much of it polemical, devoted to speculation as to the proper form and content of such contracts. (None of the later contractarians conceived of the relation between the people and the government, the ruled and the rulers, in contractual terms.)

Only toward the very end of the medieval period did political philosophers again fix attention on the way society—or particular societies—originated. They posited a state of affairs that existed before political society was organized and pointed to a contract or agreement among individuals as the most probable explanation of the transition from the one condition to the other.

The Spanish writer Salmonius, for example, argued in a book dated 1544 that both political society and law arise from mutual pledges between individuals who "come together" for these purposes. The Spanish Jesuit Juan Mariana, writing in 1599, described a prepolitical age when men lived as individual nomads, without positive law or government. These came into existence through a mutually binding "compact of society" in which, with an eye especially to the defenselessness of infants and children, they recognize the necessity of common measures of protection against acts of violence and set over themselves, as ruler, a man conspicuous for his justness and uprightness. Mariana's Protestant contemporary George Buchanan put forward a similar theory in Scotland in 1579. In all three cases, we are tempted to conclude that we stand in the presence of ideas that are indeed first cousins to those of the modern contractarians. This is true, however, only in the sense that the late medieval contractarians anticipated to some extent the vocabulary of Hobbes and his successors, and, by speaking in terms of contracts between persons, also anticipated to some extent the emphasis on individual consent.

But a vast chasm yawns between Salmonius, Mariana, and Buchanan, on the one hand, and Hobbes, Locke, and Rousseau, on the other. The former, though they posited "prepolitical" men, conceived of them as possessing duties and rights under divine and natural law; far from insisting upon the "prepolitical" condition as "natural" in

contrast to the political condition, which is a human artifact, they deemed the political condition the more natural of the two because it is necessary for man's perfection and because ultimately it is the handiwork of God. The motives they attributed to men for "coming together" are by no means exclusively selfish and utilitarian (they include self-protection and self-preservation, but not as the supreme motive). Finally, they had no difficulty in explaining the binding character of the contract, since both divine and natural law enjoined the keeping of promises. When, moreover, the Roman Catholic writers of the medieval period spoke of political society as contractual in origin, the point they were making obliquely is that political society is *merely* contractual in origin and therefore inferior to the church, which they believed to have come into existence through a direct act of God.

### Contributions to democratic theory

Hobbes, Locke, and Rousseau have much in common besides their use of the compact, or contract, between individuals in a "state of nature" as a device through which to communicate their major teachings about politics. There are, of course, also great differences among the three, some of them topics of continuing controversy among scholars of political theory; this controversy has become enormously complicated. Each of the three philosophers wrote several works on politics, in which apparent inconsistencies, contradictions, and shifts in position on particular issues can be found, so that no scholarly consensus exists as to precisely what any of them taught. Each, in large part on the basis of testimony from self-proclaimed "disciples," has come to be identified with this or that subsequent political event or movement (Hobbes with modern authoritarianism and dictatorship, Locke with constitutional democracy, Rousseau with the French Revolution and "absolute" majority rule), so that the controversy in question has to some extent been affected and sometimes exacerbated by the political sympathies of the commentators. Finally, each of the three—at least according to recent scholarship—expressed himself on occasion with something less than complete candor, so that there is now dispute as to where we are to look, even in one and the same book by one of the three, for the passages in which the author expressed his "true" intentions, as distinguished from those allegedly included for the precise purpose of throwing the general reader "off the scent" or enlisting the reader's prejudices on behalf of the author's position. If, however, we

fix attention exclusively on each author's definitive work dealing with the contract and related topics (for Hobbes, *Leviathan*; for Locke, *The Second Treatise on Civil Government*; for Rousseau, *The Social Contract*) and think of the three together as a school and as a bridge leading from traditional political philosophy to modern political science and if we concentrate on the concept of contract itself, as it evolved from Hobbes to Locke to Rousseau, some conclusions are warranted about the similarities and differences between them and about their contributions to the emergence of present-day democratic theory.

**Individual rights.** For each of the three authors the individual's right of self-preservation and of choosing the means thereto is that which authorizes the individual in the state of nature to enter into an agreement to form a political society and, so, legitimates the contract. For Hobbes and Locke, however, that right was a "natural" right, which belongs to the individual in the very "nature of things"; both regarded the proposition that asserts the right as requiring demonstration, which for each of them took the form: People as we know them, as given to us by nature, act *as if* they possessed such a right; therefore they do possess it. The mature Rousseau of the *Social Contract* attempted no such demonstration, preferring to treat the right to preserve oneself as axiomatic and, above all, as not a natural right. To Hobbes, therefore, belongs the credit for having taken one great step toward contemporary democratic theory by having made of the problem of the right or rights of individuals one of the central problems of modern political philosophy; to Rousseau belongs the credit for having, in anticipation of contemporary democratic theory, freed the defenders of individual rights from the necessity of rooting them in "nature."

**The law of nature.** Hobbes and Locke both appealed to a "law of nature," which for Hobbes defined the minimal rules that, in the very nature of things, men must agree to observe if they are to constitute a society that will really protect them against the dangers of the "state of nature." For Locke the law of nature defined men's rights and duties in the state of nature and was, therefore, the ultimate source of the individual's right, once within civil society, to protection of his "life, liberty, and estate." Both, in any case, revolutionized traditional natural-law teachings, by giving to the law of nature a new meaning and a new content. [See NATURAL LAW.] However, it was the Rousseau of the *Social Contract* who took the drastic step in the

direction of contemporary democratic theory: he jettisoned the "law of nature" altogether and argued that there is no objective standard that the positive law of a particular society should seek to approximate.

**Authority and legitimacy.** Hobbes's contract commits the individual to permanent and irrevocable membership in a political society, whose first and only task, once it is constituted, is to name a sovereign (either a single man, or an oligarchy, or a democratic assembly) who is empowered to make laws, decide disputes, lay down principles of right and wrong, and distinguish between religious truth and heresy; once the sovereign has been named, the citizen owes him absolute obedience in return for that protection against domestic law violators and foreign enemies which allegedly makes of civil society a "good bargain" for the citizen by comparison with the "violent death" that is his well-nigh certain fate in the state of nature. The effect of the contract is to make the will of the sovereign "representative" of the citizen's own will; the sovereign disposes of the entire force of society for effectuating his will, and the citizen, because that is what he has contracted to do, wills every act of the sovereign that does not involve direct sacrifice of his own life. The sovereign, not himself a party to the contract, cannot "rightfully" be called to account by his subjects for the manner in which he performs his task. The individual, although he comes into the contract by virtue of his right of self-preservation, enjoys within society only such rights as the sovereign wills him to have. The Hobbesian model anticipates modern democratic theory only in the sense that it makes of the "people" the remote source of all governmental authority.

In Locke's conception of the contract the individual also assumes a permanent and irrevocable obligation to obey the legislative that the society appoints in its first act following its institution, though only provided that that legislative act for the "public good."

Some commentators, however, have construed that proviso as guaranteeing to the individual rights that the legislative must not invade or deny, upon pain of exceeding its rightful authority (so that, according to these commentators, political power under the Lockean contract is "limited"). Other commentators have dismissed the proviso as operationally insignificant, since the contract neither specifies the rights in question nor envisages machinery through which the individual might assert them (so that, according to these commentators, Locke's legislative is, from the

standpoint of the individual, no more "limited" and, thus, no less absolute than Hobbes's sovereign).

The decisive difference between the Hobbesian contract and the Lockean is that under the latter the "people," when it finds that the government is violating its "trust"—that is, the obligation to act only for the public good—may rightfully resist the government's authority and overthrow it, though the people must proceed at once to install a new legislative, whose laws the individual citizen, still under the "original" contract, is obligated to obey. If we deem the authority of Locke's legislative to be a limited one, without power to deny or invade certain individual rights, we may say that Locke's contract points forward to the bills-of-rights emphasis in contemporary democratic theory.

Rousseau's contract differs radically from Locke's in two decisive respects. Rousseau's individual, when he enters the contract, cedes all of his rights, including his property, to the community, with the clear understanding that he is henceforth to enjoy only such rights as the "general will" of the community vouchsafes to him and is to perform all duties that that general will imposes on him. Rousseau's contract, on the other hand, is not permanent and irrevocable: the "general will"—that is, the body of the citizens in their legislative capacity—must legislate only laws which are general in their purpose (that is, addressed to the common good of the society's members) and general in their application (that is, of such character as to extend the same rights to, and impose the same duties on, each citizen). When the citizen finds himself in the presence of a law that does not meet these requirements, the contract has been violated and its obligation lapses. Rousseau said nothing about the situation that would supervene on such a violation of the contract; but it is certainly Rousseau's "model," not Hobbes's or Locke's, that points forward to the quest in contemporary democratic theory for a legislative process involving procedural guarantees, whose observance the citizens may demand with the threat of withdrawing their obedience. In other words, Rousseau's conception foreshadows the constitutional emphasis in contemporary democratic theory.

**The problem of consent.** As a corollary to the right of self-preservation, Hobbes, Locke, and Rousseau held that a man can be rightfully "bound" only by his own consent. All three encountered great difficulty in explaining why the contract to which the original contractors consent should be binding upon their descendants. Hobbes and Locke "papered over" this difficulty by asserting that the descendants give tacit consent by remaining within

the community and accepting its protection. Neither Hobbes nor Locke, viewed from the standpoint of contemporary democratic theory, made any serious attempt to carry the principle that a man can be bound only by his own consent over into the "model" of political society.

Here, once again, Rousseau broke sharply with his predecessors and sought in two ways to legitimate the laws of his society by the continuing consents, individually given, of the citizens: first, by stipulating in the contract that each citizen shall be required, on coming of age, to opt for consenting to the existing institutions or for withdrawing from the society, and, second, by requiring that no citizen be formally excluded from the deliberations and votes that produce expressions of the "general will." In both these respects, Rousseau brought us very close to two of the major themes of contemporary democratic theory: the emphasis on political equality and the stress on active participation by the citizens in the political process as an indispensable condition for "government by consent."

## SOCIAL CONTROL

### I. THE CONCEPT

Jesse R. Pitts

### II. ORGANIZATIONAL ASPECTS

Amitai Etzioni

#### I

#### THE CONCEPT

Much of the impetus for the development and use of the concept of social control comes from the sociological adaptation of the Darwinian tradition. But there, however, the major dichotomy was between organism and nature; for the various theories of social control, it has been that between individual and society. It is assumed in these theories that society has to control the animal nature of man: if order is to be established and main-

tained, man's tendency to pursue his self-interest to the point of a war of all against all must be limited through learning or selection, or both. Emergence of the concept of social control thus indicated a waning of the utilitarian concept of the natural harmony of self-interests.

Although social control is essentially an American term, it has its functional equivalents in European sociology. Durkheim saw the *conscience collective* as constraining men, with a power directly proportional to the intensity of the interaction around its specific representations, to behave in certain ways regardless of their own selfish interests. Thus a major function of social institutions such as the family, marriage, and religious cults was to increase the constraining power of the *conscience collective*; institutions were essentially agencies of social control. Implicit in Durkheim's account of society was a concept of deviance as caused by "animal spirits": without social constraint men were prone to violence and to selfish calculations, as typified by *suicide égoïste* and economic *anomie*, or to the infinite pain of infinite desires inevitably frustrated, as typified by *suicide anémique* [see SUICIDE, article on SOCIAL ASPECTS].

In consequence, Durkheim advocated, as a means of social control over the *anomie* endemic to economic life, the development of professional organizations, in which intense interaction would result in the development of realistic codes of behavior and in their enforcement through constraint upon the conscience of each of the participants.

In *The Rules of Sociological Method*, first published in 1895, Durkheim pointed to another source of deviance: "premature" compliance, like that of Socrates, with currents of the *conscience collective* that have not yet reached the common man. This is essentially a structural approach to deviance; in Merton's famous article (1938), this same approach issued in the concept of deviance as adjustment to the inner contradictions of a given social system rather than as an expression of untamed impulses. Here, however, the resulting concept of social control was not as well elaborated—that is, unless we are satisfied with a more or less explicit concept of social control that limits it to purposive, rational social change aimed at removing these inner contradictions.

In fact, this has long been the approach of American sociology, especially in its early melioristic days. Ross, who is responsible for the popularity of the concept "social control" (it is the title of a book of his, published in 1901), described many of the themes that were to dominate American soci-

ology until the late 1930s. First, there was the concept of the "natural order" derived from the spontaneous meshing of men's personalities with their inherent capacities for sympathy and sociability, on the one hand, and from their sense of justice and capacity for resentment, on the other. Some of these capacities were seen as biological endowments, but the "sense of justice" was thought to be derived from the early development of self not only through interaction as such but also through the resultant internalization of the other, which results in a desire to behave toward others as one would want others to behave unto oneself. Baldwin (1895) was cited by Ross for an early version of a concept that has been attributed solely to Cooley—the "looking-glass self." "Natural order" is thus similar to the state of the primary group as described by Cooley (1909), a state that the Chicago sociologists of the 1920s and 1930s believed was disrupted by urbanization, immigration, breakdown of the small community into competing groups, decline in the efficacy of natural selection (which used to eliminate "moral idiots"), and deviant behavior on the part of men with backgrounds different from those of the original settlers. As examples of natural order Ross cited primitive societies and even such modern settings as the California mining camp, where he thought social and economic equality had reigned before the coming of "adventurers and broken men from all parts of the world" (1901, p. 43).

As Martindale (1966) has noted, social control in Ross's work has many features of social contract, since Ross defined it "as concerned with that domination which is intended and which fulfills a function in the life of the society" (1901, p. 16). Yet when he described social control in action, he fell back upon all the forms of the Durkheimian *conscience collective* that constrain the individual: public opinion, law, belief systems, education, custom, religion, personal ideas (among others, the basic definitions of manhood or womanhood), ceremony, art, personality (i.e., charisma), values, creative elites. The dilemma of the social behaviorist (at least since the time of Lester Ward) is thus clear from Ross's work: on the one hand, there is a Puritan assertion of the importance of the individual, especially of the individual with the proper instincts, as contrasted with the "moral idiots or moral lunatics who can no more put themselves in the place of another than the beast can enter into the anguish of its prey" (*ibid.*, p. 50). These individuals can and should create a moral rational order to replace the natural order rendered un-

viable by greater population density and heterogeneity. On the other hand, Ross maintained that purposive social action, to be effective, must take into account the nonrational elements of social living, which may have Darwinian rationality, if not humanitarian rationality, on their side. But it is never made very clear how we move from the unintended but functional constraint of custom, religion, etc., to an "intended" and even more functional form of social control. Thus, in Ross's discussions of social control we encounter either a description of the elements of social constraint—a field that is equal to the whole of sociology—or pious wishes for rational action, which do not make particularly interesting reading.

W. I. Thomas, as would be expected from one who saw social structure as social definition of the situation, used the concept of social control extensively. He agreed with Ross that once society had moved away from primary group control, the problem was to develop rational controls. Thomas saw social control as emerging from the actions of a new type of man, schooled according to the theories of the philosopher John Dewey and therefore capable of creating new patterns as they were needed (see Thomas & Znaniecki 1918–1920; Thomas 1923). Park and his colleagues (1925) were also concerned over the shift from primary means of social control, such as the family, the neighborhood, and the community, to secondary means of social control, such as the police, the press, the political machine, and the courts. Park pointed out that intended control did not necessarily mean rational control, in terms of the utility of the total community. Drawing on another tradition, Mannheim (1935; 1950) again raised the question of social control through planning and contrasted it with classical liberalism, which could not secure controls over custom and the laws of the market. For him there was a sort of fixed quantum of social control: when some forms of control diminished, it meant that others were increasing, in accordance with what he called the "laws of transmutation." Since controls were unavoidable, the attempt to deny rational, conscious control meant surrendering to nonrational, unconscious controls or to interest-group manipulations.

It is with Parsons (1951) and LaPiere (1954) that we see the concept of social control become systematically limited to the control of deviance. This approach to the concept eliminates from it the ordinary normative component consisting of social structure and, more specifically, the aspects of social structure that are concerned with socializa-

tion. A still more narrow definition is that of *Sociological Abstracts*, which reserves the rubric of social control to penology and the sociology of correction problems.

Parsons' concept of social control is particularly fruitful because it is a systematic attempt to derive consequences from a specific theory of deviance. First, deviance is defined by "its tendency to result either in change in the state of the interactive system, or in re-equilibration by counteracting forces, the latter being the mechanisms of social control. It is presumed . . . that such an equilibrium always implies integration of action with a system of normative patterns which are more or less institutionalized" (1951, p. 250). Leaving aside the problem of error as deviance, Parsons addresses himself to the genesis of deviant motivation, which, in his opinion, is not to be found in "animal spirits" but results from (1) the learning derived from past interaction, (2) specific personality factors, and (3) the pressures and opportunities of immediate interactional situations. When role expectations are frustrated, the motivation of the actor is likely to develop ambivalence. Ambivalence means that the motivation of the actor contains both conforming and alienated components that may be directed at the normative pattern and/or at the relation with the social object (alter). The ambivalence can be oriented to an alter who, as a past satisfactory source of role reciprocity, had become the focus of positive feelings but who now, as a frustrator, becomes a source of negative feelings. Or it can be oriented to the norm that heretofore regulated the relationship between ego and alter and that has been internalized by ego, especially if the norm is seen as responsible for the frustrated role demand.

Ambivalence can result in three courses of action: first, the loss of any attachment to the object or the pattern (a movement from ambivalence to indifference); second, a compulsive expression of only one side of the ambivalence, compulsive because it must inhibit the unexpressed side; and third, the acting out of both the conforming and the alienated sides in contexts that are segregated in time and place. Although Parsons does not say so outright, one is led to the conclusion that the personality system will normally take the third course and try to discharge both components of its motivational states. If this is not possible, the result is more likely to be either compulsive conformity or compulsive alienation. And it is to these two last eventualities that Parsons addresses himself. Passivity-activity, compulsive

conformity versus compulsive alienation, and orientation to patterns versus orientation to social objects are the three major dimensions explored in his analysis of deviant behavior.

This analysis results in the following insights. First, what may on the surface appear to be a conforming disposition may be so shot through with repressed alienation that as a result it is rigid, characterized by attempts to dominate the situation without due regard to the needs of alter. As a result, it is likely to be either deviant or deviance-prone. Second, since illness is a prototype of passive alienated behavior, it must be considered a pattern of deviance. Thus its incidence, form, duration, and so on, become susceptible to sociological analysis. [See ILLNESS; MEDICAL PERSONNEL, *article on PHYSICIANS*.]

Turning to the situational aspects of deviance, Parsons mentions role conflict and value conflict. His insight here is that values, especially of the universalistic-achievement type, lend themselves to deviant orientation because they permit much leeway in interpretation. Thus we have deviant groups able to claim legitimacy as conforming to the "real" values of the society, and this in turn permits deviants to express both sides of their ambivalent motivation: conformity to their own group and its norms, together with alienation from the outside world and its norms. A good example of this is the radical Christian sect.

Although Parsons seems to believe that the grouping together of deviants increases their danger to society, he sees an ultimate source of social control in their ambivalence and in the bridges that these utopian or radical groups maintain to the main value pattern by claiming to be its real defenders. These bridges are the basis for the "selling out" that many members experience after a more or less protracted stay in the deviant organization.

Related to the deviant group's search for legitimacy is the "secondary institution," such as the youth culture or organized gambling, which allows some deviance from the dominant value pattern and yet keeps the participants integrated with this pattern. It is the prototype of institutions that both permit some expressions of alienated feelings and bring the actors back to conformity. [See GAMBLING.] Such, too, is the function of bereavement rituals [see DEATH]. The secondary institution also *insulates* the deviant pattern and limits its impact on the rest of the social system. Insulation as a means of social control is to be contrasted with isolation, the latter aiming to forestall the grouping of deviants. An example of isolation is what

occurs in the treatment of physical illness, for instance, although the treatment of illness as a whole is an example of insulation. And it is precisely in relation to the description of illness as passive deviance that Parsons makes his major contribution to the theory of social control. Taking the psychotherapeutic model as the prototype of the social control response to illness, he sees this process as including the following steps: support, permissiveness, restriction of reciprocation, and, finally, esteem for resuming conformity (Parsons 1951, chapter 7; Parsons & Bales 1955, pp. 38-41).

The relationship of this therapeutic model to the structure of social learning is clear. Social control, when it aims to alter the state of the actor's motivation (rather than merely introduce the situational component of reliable and harsh negative sanctions) will follow the psychotherapeutic paradigm, most often quite unconsciously, and this will happen both at the level of dyadic encounters and at the level of institutional patterns, such as the bereavement rituals mentioned above.

The following analysis of social control stems from Parsons' insights, but it focuses more on the institutional aspects and less on the motivational aspects of the problem. Thus, its main concerns are the institutional patterns that attempt to head off deviance by (1) preventing the buildup of tensions that result in a desire to deviate; (2) reinforcing the desire to conform; (3) making clear what is socially appropriate; (4) discouraging deviation by reliable negative sanctions and rewarding conforming behavior; (5) modifying social patterns to accommodate as much as possible the deviating behavior of actors.

Finally, a description is given of the "fringe organization" as one type of Parsons' secondary institutions, and it is shown that fringe organizations have functional aspects for society even when they seem to give deviants the power of coalition.

### Preventing the buildup of tensions

Prevention of the desire to deviate is, of course, one of the major functions of socialization. What is relevant here is the existence of structural arrangements for draining off tensions that otherwise might trigger deviant behavior. The buildup of tensions in an individual, caused by the inability of role behavior to reduce psychological need dispositions, makes him vulnerable to regression, i.e., to behavior which is not value-oriented and which is incompatible with his normal age, sex, and status roles but which would reduce these tensions. Hence, institutional arrangements have to allow regressive behavior either in isolated situations or

in crowd situations where the behavior gains temporary legitimation through the collective aspects of the behavior, and yet the temporary character of the crowd clearly marks the irrelevance of the behavior for normal situations. This is preferable to the development of latent alienation in conforming behavior.

Primary groups, of course, offer this relative isolation. In fact, role behavior within them requires a capacity to regress and/or to tolerate this capacity to regress in others. Parenthood and conjugal relations are examples of primary group behavior where a capacity to regress—identification with the child, for instance—is an important motivational facility. Family roles offer a most important sanctuary for much tension reduction and behavior that would not be tolerated in a public context. As a matter of fact, one of the most effective agencies of social control is the family, as indicated, for instance, by the finding that marriage is one of the action patterns that has the most positive rehabilitative significance for a young jail or penitentiary releasee (Glaser 1964).

Other modes of releasing tensions are the various forms of entertainment and play through which catharsis of antisocial desires can be secured. The "party" is a sort of institutionalized crowd situation where consumption of alcohol testifies that behavior "under the influence" does not imply a lasting commitment of the self to the pattern being indulged in at that moment. Saturnalia such as the German *Fasching*, carnivals, Halloween, and office parties perform similar functions. It is interesting to note that the wilder parties are typical of the lower-class males, the young of all classes, and the more cosmopolitan of the middle and upper classes. In the lower classes and among the young the problem of role frustration is acute. In the upper classes the opportunities for regression with immunity are at once a mark of class membership and a class asset.

The development of labor discipline in mass industry seems to have paralleled the development of mass entertainment, as if the tensions induced by the former could be endured only if the latter were available to provide release. Urbanism by itself creates many crowd situations where tension release can be secured. The development of the saloon offered an opportunity for adult peer grouping where a certain adolescent irresponsibility could be recaptured, and although it led a certain percentage of workers to alcoholism and family nonsupport, its over-all effects must have been to reduce working-class tensions.

Entertainment, through art, literature, films, or

television, has a social control impact that well illustrates the mechanisms described by Parsons in his psychotherapeutic paradigm. By showing the hero as subject to some foibles, the various art forms offer support and permissiveness. They allow the spectator to have a deviant fantasy without burdening him with isolative guilt. Art must follow canons of taste, and the audience has the duty to take a critical attitude toward the show. Accordingly, regression through entertainment is allowed only because entertainment finally sends the audience back to its cultural responsibility, and through this to its broader social responsibility (for one of the best accounts before Freud of art as social control, see Ross 1901).

Participation in the family, in peer group roles, and in entertainment roles acts as a powerful agency of social control, not only through the surveillance and sanction systems present in the primary group but also through the opportunity afforded the individual to give vent to motivations that cannot be accommodated in secondary group roles. Hence, it is possible to say that all work and no play can make Jack a deviant boy.

Religious services also act in this way, more obviously in the case of revivalist services. Such services not only reward conformity but also, through the function of the church as a "social placer," stress rewards for proper motivation, regardless of actual success. Thus churchgoing decreases the sting of failure by stressing the secondary importance of success in this world. If it did not, failure in this world might impel the individual to give up his conforming motivation. In this context it would be interesting to compare the rates of deviance of the western European working class with those of the American working class. The former has had the benefit of the secular religion represented by revolutionary socialism, while the American working class is largely bereft of this "Catholicism of the poor." Socialism has removed the sting of failure from the urban proletarian condition. It has promised the workers special dignity in the socialist paradise if they keep on being deserving—which, in addition to joining political organizations, means rejecting a difficult, if not impossible, upward mobility and abstaining from the deviance seen as characteristic of that lower-class stratum which Marx called the *Lumpenproletariat*. Thus conformity for the socialist working man is not incompatible with dignity. The American working man, on the other hand, caught in a Puritan ethos of striving and with no sedative for the pains of failure, may well be prone to take the law into his own hands, i.e., strike out against the prevailing

system through various forms of white-collar or blue-collar crime.

A functional and partial equivalent of the Catholicism of the poor is the gambling complex (Bloch 1962, Parsons 1951), which redefines life chances in terms of the "break": thus, one's status in life is not one's own fault, since the same luck that puts you down may raise you up [see GAMBLING].

### Reinforcing the desire to conform

The reinforcement of the motivation to conform was one of Durkheim's major concerns. He saw social control (which he called social constraint) as derived from collective representations; its strength was directly related to the size of the group that shared those representations and to the intensity of the interaction between group members. All social institutions, according to Durkheim, had this function of heightening the strength of collective representations through increasing the rate of interaction. Ritual, on the other hand, increased the sameness of the shared representations at the same time that it grouped together masses of people (Durkheim 1912).

It is not necessary to accept Durkheim's interpretation of the mechanisms whereby this heightening of the constraining power of collective representations takes place in order to accept the statement that ritual does act as a reinforcer of conforming motivation. It makes the actor feel part of an all-enveloping group that shares his attitudes and with which he can think of himself as standing in a primary-type relationship. The actor's good standing in such a group depends upon his continued commitment to the symbolic system evoked by the ritual.

A rationally oriented society is certainly not free of ritual. One of the dimensions of mass entertainment is ritual. Rites of passage, such as commencement exercises, make clear to the individual that he has changed groups and that he must not regress to behavior which might have been proper for the group he has left but is not functional for the groups he has entered.

Ritual operates as an *emblem of membership*. In modern society the commitment to the over-all community, a necessary but not a sufficient condition for commitment to its inner role structure, is stimulated by collective movements that demand the expression of conventional sentiments. These collective movements are triggered by dramatic events such as Lindbergh's flight to Paris, President Kennedy's funeral, or any dramatic event where common feelings are aroused in many people. Press, radio, and television are crucial to this

process. At such times the nation becomes palpable to the individual. How often these movements are necessary and what form they take deserve more research than has been forthcoming heretofore (see, however, Shils & Young 1953; Greenberg & Parker 1965).

Finally, the extension of education has greatly reinforced popular commitment to the nation's values and norms. As modern society allows and demands ever-increasing initiative from the individual rather than binding him to traditional role expectations, the more imperative it becomes for society that individual commitment to values and norms should be thorough.

In situations where role behavior is largely invisible and/or where the alter of the dyadic relation is unable to evaluate whether ego is really upholding his end of the bargain, a long educative process is as necessary for building value controls as it is for imparting technical skills. This is true of most professions. Such occupations as watch and television repair, in which role behavior is also invisible, do not get this expensive value training, with the result that deviance is much more extensive in these trades than in the professions.

### Clarifying the content of conformity

Reinforcement of motivation is of little avail in forestalling deviance if there is ambiguity as to what is conformity and what is deviance. While there are always some areas of anomie in any complex society, an additional hazard is the pressure that the individual generates against the norms through developing idiosyncratic definitions of the situation—definitions that legitimate for him behavior that to others seems clearly deviant (Sykes & Matza 1957).

Primary groups have the capacity, through their close contact with their members and the high rate of communication which prevails among them, to make very clear what is desired or what is proscribed behavior. By confronting the individual's inipient idiosyncratic definitions of the situation with its own definitions, the primary group brings the individual back into line. There are areas of behavior, however, where individuals can become quite isolated from all primary groups, and thus without seeming to be. Marginal groups are especially prone to this invisible isolation. Cressey (1953) has shown how the first-time offender is often a man who becomes socially isolated with respect to a financial problem because the very existence of the problem already involves deviance from status group norms. Around this "isolated deviant problem" as Cressey calls it, the individual devel-

pliance is solved by treating the conformist to the ideal norm as a "hero"—a positive deviant, but a deviant nevertheless. Thus the average member is relieved from the guilt of nonconformity, and there is little development of counteraggression against the ideal norm. Military peer groups may say "Never volunteer," but nevertheless enough soldiers do.

**The law as ideology.** The law has been used, especially in the United States, as a promoter of various kinds of social changes. This is equivalent to treating the law essentially as a statement of ideology. At the present time the federal government of the United States is using law as an instrument for changing the social status of the Negro in the South and, to a lesser degree, in the North. Although Sumner's classic critique (1894) of the "absurd effort to make the world over" still holds true in general, there are nonetheless situations where law judiciously enforced can act as an agent of social change. To take the Negro civil rights issue as an example, it requires, first, the growth of ambivalence in Southern commitment to the caste system and a growing number of supporters for the federal position among the white population. Through judicious enforcement of the law the federal government can create situations in which the Southerners committed to the caste system find enforcing its norms too costly and therefore begin to look on surrender as honorable, because it is into the hands of impersonal but respected powers such as "the court" and "the law of the land." Every failure of the caste system to enforce its norms decreases the power of these norms; every success in enforcing the federal norms strengthens these norms. However, the federal norms, being supported only by a minority, require for their enforcement a reliance upon force that is expensive and partly self-defeating, because force clearly reveals how little support they enjoy from the local mores.

The role of the law as a specifier of the proscribed is fully discussed elsewhere [see *Law*]. One aspect of this role that deserves special mention here is the contradiction in which the legal process finds itself. In the trial the lawyer defends the law against such deviant tendencies of the state as its propensity to abuse its power in order to secure what it believes to be desirable community ends. The lawyer accomplishes this by forcing the state to follow the rules of evidence and the inherent logic of the legal codes. Through his success the majesty and sacred character of the law are reinforced, especially among the middle classes, who

can comprehend the logic of these procedures (though more often through the way in which they are represented by television and the movies than through any actual witnessing of them). On the other hand, it is a natural consequence of the legal process that a certain number of criminal deviants fail to be convicted and punished. Knowledge that this is so weakens the authority of the trial in the eyes of spectator and culprit alike. It increases the pressure for "police justice," or the informal disposition of cases by policemen on the spot. It also increases reliance upon the informal sanctions of the social class system. Acquittal in court comes to mean not innocence, but that the state was unable to prove guilt.

### Reinforcement of the sanction system

Sanctions can be negative or positive, that is, they can punish deviance or reward conformity. Most of the rewarding of conformity takes place through the regular role meshing and role reciprocities of the social structure. It is in this sense that Durkheim is right: all aspects of social structure have a part to play in social control. Here, however, we are primarily concerned with sanctions as deterrents. The effectiveness of a sanction system in discouraging deviant behavior is, we may suppose, directly related to the strength of the sanctions and to their reliability. In fact, if we extrapolate the findings of Lazarsfeld and Thielens (1958) concerning college professors under the cross-pressure of left-wing peer groups and right-wing Congressional investigating committees, we can add that the reliability gradient of sanctions may be more important than their severity gradient. For instance, the difference between the rates of stealing in rural and urban districts, other factors being held constant, can be partly explained by the comparative ease of hiding stolen property in the city because of the lower surveillance capacity of the collectivities in which the urban deviant spends his life. In the city, neither physical proximity nor constant visibility implies a primary group concern for or interest in alter. Thus, detection and negative sanctions are easier to escape in the city even while the symbolic potential of the mere possession of goods increases. There is little knowledge of the owner's roles outside of the property context, and specialized agencies such as the police cannot duplicate the ubiquitous surveillance of long-established neighbors with firsthand knowledge of each other's financial capacities. Hence, the higher the turnover of neighborhood membership, the greater the penetrability of primary groups

(and the greater the ease of departure from them), and the weaker the negative sanctions against all forms of misappropriation of property. For instance, the Chicago racketeer can become a respected real estate operator on the West Coast. To cope with the problem of the invisible past in a mobile society, state and private organizations have developed their own system of investigation, in which the secret personal file has replaced fallible public reputation.

Class discrimination is more effective the closer one comes to the upper-class status group because, at that level, numbers are comparatively small and contacts are maintained through a high rate of sociable interaction and entertainment. As a result, in such circles reputation is more effectively used as a mechanism of social control. For instance, arrest and imprisonment are not a serious disgrace to the lower-class deviant, since he shares in a contraculture, one of the functions of which is precisely to neutralize the impact of such public degradation or loss of self-esteem. But arrest and imprisonment are major catastrophes to a middle-class deviant or to anyone not defended by a delinquent contraculture or subculture.

Thus class sanctions are among the most effective sanctions available for social control. They often act as agents of social control even among those whose self image is one of inured criminality; for instance, it is rare that criminal fathers will not attempt to raise their children to be "straight." Wives and children are the hostages of the class system, and many a criminal has retired from crime, many a conformist has remained a conformist, because of the fear that his family would suffer negative sanctions if his deviance should become known.

The upper class exercises powerful control over the successful entrepreneur of lower-class origins who attempts to continue the self-seeking and deviant orientation that has been so profitable to him in the past. By forcing the upstart's family into a marginal position in which the children are led to judge their parents by standards that the parents cannot learn, the upper class fosters tensions that have literally destroyed many such families. Indeed, the effectiveness of this kind of class system as a sanctioner derives from the fact that it does not debate with the individual as to his guilt or innocence. Instead, it acts upon the basis of reputation and of its members' response to the actions of the individual in question. Since the individual grants legitimacy to the class he aspires to join, his anxiety, generated by the invisibility of his

judges and by the uncertain incidence and magnitude of their sanctions, causes him to undergo anticipatory socialization and to overconform well before he receives the rewards of membership. [See REFERENCE GROUPS.]

Social class sanctions do not require the promise of social mobility to be effective. In fact, a high rate of social mobility may reduce the screening capacity of status groups. In low mobility systems the upper social classes confer esteem on selected lower-class families for their outstanding conformity and thereby raise the latter's standing within their own status groups. A weaker class system, such as *may* exist in the Soviet Union, requires, for the functional equivalent of social class sanctions, the systematic surveillance of the citizen by the state through a large police force, much of it secret, assisted by the citizen militia, factory committees, wall newspapers, and the like. To be as effective as social class sanctions, this kind of surveillance, in its arrest and trial procedures as in all else, must be as one-sided as is the court of social class.

Although social classes share certain broad judgments as to the severity of crimes, they do not agree on the evaluation of certain points of behavior. Each social class has its private culture as well as its private language. For instance, some upper-class groups tolerate extramarital sexual patterns that would be considered deviant by the classes beneath. One of the reasons for this upper-class tolerance is precisely the intolerance that prevails among the classes beneath them. Lower-class deviants are sometimes protected by upper-class persons merely in order to degrade the middle-class standards that these deviants have transgressed. Thus, any exacerbation of the class struggle weakens the efficacy of the class system as an agency of social control.

**Force as negative sanction.** The main asset of primary groups and of the status system as agents of social control is that their sanctions are pervasive in their incidence and impact and that even the deviant is usually highly motivated to maintain group membership. Accordingly, the most drastic sanction at the disposal of these groups is ostracism, which can use force, although it does not usually do so. More often, legal use of force is the monopoly of the state. In any case, force always stands behind the penalties meted out by the apparatus of justice, even when these penalties are merely fines and damages. Force is, of course, the ultimate deterrent and a most powerful means of social control. It can prevent an individual—either

directly, through incarceration or death, or indirectly, through threats—from doing something which the state forbids. In fact, force seems much more effective in prohibiting action than in promoting active conformity. As soon as role tasks take on any sort of complexity, they require a degree of cooperation on the part of the individual that force alone cannot secure. Force can only coerce the visible—the body and its movements—while cooperation, which involves the use of intelligence and good will, is invisible. It is difficult for force to secure cooperation in the sense just described unless the following two conditions are met: (1) members of the deviant's primary groups can be used as hostages, or the deviant can be blackmailed, explicitly or implicitly, through the possibility that he may be expelled from cherished reference groups; (2) the use of force reasserts the legitimate authority of him who uses it by certifying that he takes his responsibilities and convictions seriously.

The deviant can also be compelled by force to participate in roles where force is not a major aspect of the interaction. Such roles may have, as will be seen from the discussion of prisons, a socializing influence. At one extreme is the "brainwashing," the effectiveness of which seems to have been exaggerated, which took place in the Chinese prisoner of war camps in Korea. At the other extreme is the therapeutic relationship which commitment to a mental hospital may permit. But once childhood is over, punitive justice is the only expression of force that most citizens of modernized societies are ever likely to experience. Force certainly has a bad reputation in intellectual circles, and it is true that punitive justice acts at least as much through the stigma carried by its penalties as through its incarceration or rehabilitation programs. By stigmatizing the deviant, punitive justice passes on to him the pervasive sanctions imposed by the primary groups and by the status system. For those who no longer wish to belong to the community of the righteous, these secondary sanctions are meaningless; in fact, to have served a prison term can, in the "negative status group" composed of fellow deviants, be a claim for prestige. But secondary sanctions act as powerful threats for those who conform primarily because they are afraid of downward mobility. The latter not only fear the sanctions of punitive justice but even come to look on avoidance of these sanctions as a reward for conformity. The more gruesome the imagination of what the deviant endures, the stronger the conformist's "relative appreciation" of his own fate. As a matter of fact, the imagination is often worse

than the reality, since those who feel but resist temptation usually stay as far as possible from the areas where they might develop a realistic knowledge of punitive justice.

Those who insist most vehemently that the brand on the deviant should be deep and lasting are likely to be those for whom the tangible rewards of conformity are relatively few and for whom virtue must too often be its own reward. Frequently they are the ones who live closest, in terms of social distance, to the lower class, from which most blue-collar criminals issue. They are middle-class-oriented working-class, the "poor but honest," or lower-middle class freshly arrived from the working class. Thus stigmatizing the criminal reinforces and stabilizes their sometimes tenuous, imperfect, but often hard-earned superiority of status. Members of such lower-middle status groups, with the possible exception of primary and secondary school teachers, have not had enough education to permit them to handle ambiguity with any ease. For them the attempt to sympathize with the deviant does not imply the self-administered status reward implicit in the sophisticated forgiving attitudes that may prevail in status groups further removed from the lower class. More often they see in this attempt a degradation of their efforts to remain conforming and a denial of their social distance from the deviant. Thus, in these groups, punishment of the guilty is a reward for those who have remained innocent.

**The medicalization of deviance.** The diffusion of Freudian thought since the 1920s has had a significant impact upon the distribution of stigma and the incidence of penal sanctions.

First, it has been a force for redefining certain aspects of deviance as illness rather than crime. It is not that the act thus incriminated loses its deviant characteristics, but that the sanction considered suitable to it is no longer of the penal variety. Second, illness is no longer seen as a result of unfortunate or contingent factors, but as related to unconscious motivation. Deviants are no longer so guilty of their crimes, but neither are they so innocent of their illnesses, not only mental illnesses but physical illnesses and accidents as well. And since it is believed that there is an effective therapy for illnesses, whether mental or physical, the deviant who fails to place himself in the hands of the medical profession is guilty at least of enjoying "secondary gains" (Rieff 1959; 1966).

It has been thought by some that the medicalization of deviance has resulted in weakening sanctions to a point where individual responsibility and conformity are endangered. There is no hard evil-

dence on these points. True, the upper classes meet with less tolerance for the vices traditional to their status. On the other hand, judges will often commit the rare middle- and upper-class culprits who come before their courts to a course in therapy rather than to a stay in jail (however, these deviants may well find therapy more painful than jail, even if the social repercussions are less drastic). Lower-class culprits, especially adolescents and young adults, are more likely to be committed to mental hospitals and to find that their sentence is indeterminate. As a result, they may stay in the hospital longer than they would have stayed in jail. Szasz (1963) and other writers have stressed the threat to civil liberties implicit in present commitment and sanity board decisions.

No doubt medicalization has resulted in extending immunity from punishment to certain culprits. However, it would seem that medicalization is one of the most effective means of social control and that it is destined increasingly to become the main mode of *formal* social control. Its advantages are many. For instance, the medical and paramedical professions, especially in the United States, are probably more immune to corruption than are the judicial and parajudicial professions and relatively more immune to political pressure. This is partly due to the fact that the social distance between patient and therapist is greater than that between lawyer and client. Although the doctor has more power in his clinic than the judge has in his courts, the possibility that a patient may be exploited is somewhat minimized by therapeutic ideology, which creates an optimistic bias concerning the patient's fate. American psychiatrists are better trained for their role than American judges are for theirs. Hence, in the competition for administering formal sanctions it is possible that the medical professions will win out. Signs of such a victory would be the transfer of divorce cases to medical and paramedical boards, the end of juvenile courts, and the development of social psychiatry.

The medicalization of deviance denies the deviant the possibility of value legitimacy: If the culprit pleads illness, he thereby certifies his commitment to the dominant values and institutionalized norms and implies that, when restored to health, he will conform. Meanwhile, he must deliver himself into the hands of the medical authorities and follow their instructions in order to regain mental health. Thus the medicalization of deviance results in the political castration of the deviant.

However, medicalization does permit a less wasteful and more flexible handling of deviance.

Except for "organized" crime, such as the provision of gambling opportunities, the drug traffic, and prostitution, it is probable that most "crimes" (that is, forms of deviance classically subjected to court action) are committed by ordinary citizens rather than by members of the underworld. The disadvantage of criminal prosecution is that it can secure reliability of expectations regarding the deviant only at the price of boxing him into a stereotype that he then finds almost impossible to escape. In a sense social order, for its own preservation, *requires* him to become a stereotyped criminal. But forms of deviance that cannot be continually subjected to court action—forms that might be called the criminality of everyday life—must be ignored by the institutions of formal social control and left to the sanction of informal interaction and social class. The medicalization of deviance offers yet another possibility: social pressures on deviance can be increased without boxing the deviant into as rigid a category as "criminal."

The strength of informal sanctions is declining because of the increase in geographical mobility and the decrease in the strength of the traditional status groups. Medicalization offers a substitute method of controlling deviance—a method that is being used increasingly by universities, large corporations, professional organizations, social work agencies, and even by trade unions to control their own members and clients. The increasing commitment of the general population to absolute values—a commitment due partly to increasing education—makes a therapeutic approach more practicable. But the growing complexity of the division of labor and the increase in the zones of autonomy that are possible in the new bureaucracies (Crozier 1963) make it more imperative that the decisions which are taken by employees should be "reasonable." It is the problem of the pilot with the atomic bomb. An even greater sector of the population works with similar responsibilities. Thus social control becomes more humane and forgiving, but perhaps also more relentless and pervasive.

Although mental illness carries a stigma that may create resistance in the deviant to the role in which medicalization has cast him, it may also compel the referring authority to give the "new" patient a second chance, if the medical profession certifies him improved or cured. This can decrease the deviant's fear of being stereotyped and so reduce his resistance to treatment.

Because the medicalization of deviance is imperfectly institutionalized, there are still problems in the handling of medical files, and past treatment may become an unnecessary bar to certain

positions. These problems are likely to be worked out as institutionalization proceeds and as scientific knowledge of personality potential and effective role requirements becomes more widespread.

The medicalization of deviance has so far provided greater flexibility of response to deviance, together with more effective detection. This is partly because those who support and implement the medicalization of deviance now oppose many of the existing institutionalized arrangements for social control. Indeed, problems of control have been created in institutions such as prisons, communities for juvenile delinquents, and mental hospitals by the frequent identification of the professional with the deviant and their joint hostility to the petty bourgeois-oriented custodial staff. The unconditional rewards the professional staff offers to the deviants in order to establish therapeutic dyads, and also in order to degrade implicitly the status of the custodians, demoralize the latter, who see deviants secure favors and commercium with upper status groups that are denied to them. Their response is to sabotage the therapeutic program and try to take back the favors.

### Modification of social patterns

Social control is not exclusively concerned with trying to change deviant motives; it also operates by systematically isolating the deviant from the rest of society through the agency of such specialized organizations as hospitals, prisons, and police forces, or through that of certain relatively informal modes of organization capable of monopolizing much of the deviant's behavior and of limiting, as well as patterning, his relations with the outside world. Examples of such organizations are the doctor-patient dyad, the underworld, the delinquent gang, bohemian coterie of various kinds, and political and religious sects of such an extremist tinge that they are outside the mainstream of political and religious thought.

Hospitals and prisons, whatever else they may be, are certainly not models of conformity. Rather, they resemble such classic forms of institutional deviance as gambling, prostitution, and drug addiction, which operate under the informal supervision of the police rather than in spite of them. A mental hospital, from this point of view, is a place where mental illness is *allowed*. Another major aspect of formal organizations specializing in social control is that they control the staff as well as the inmates. Frequently, as in mental hospitals and penitentiaries, the staff lives on or near the grounds and its contacts with the outside world are few. [See SOCIAL CONTROL, article on ORGANIZATIONAL ASPECTS.]

Most work with deviants implies a capacity to identify with them that is above the average level of human empathy, and certainly a capacity to overcome the average distaste aroused by the stereotype of the deviant. Often this capacity is based upon strong deviant tendencies within the staff member, as described by the folkloric statement concerning the police: "It takes one to find one." Similar remarks could be made regarding mental hospital staff (especially professional, but also non-professional), but no solid evidence has yet been collected in this area. However, since all occupational roles that succeed in securing a high level of personality commitment must operate to reduce the deviant potential of their incumbents, the statement that any agency of social control also controls its staff implies that the staff brings to the agency a greater propensity to deviance than is met with in the average breadwinner. Impressionistic evidence of this seems strong in the cases of vice squad detectives, psychiatrists, and personnel of organizations devoted to the rehabilitation of alcoholics.

Research on this problem is urgently needed, but such research would create very serious problems of rapport and public relations for the sociologist. Nevertheless, it is useful, in order to understand the structure of these agencies, to think of them as organizations where dilemmas of administration and policy are resolved in terms of the staff's needs rather than the inmates', even though this is not intended. The reasons for this are threefold. First, roles specializing in social control deal by definition with people who are frequently recalcitrant to, and are not deemed competent to evaluate the worth and necessity of, the restraining and/or therapeutic efforts directed at them. Second, there is a tendency for the stigma that applies to the deviant to be extended to the organizations specializing in control of the deviant. As a result of both these circumstances, formal social control operates at a very low level of visibility. The receivers of control are deemed incompetent and inferior to their controllers. The rest of society is not very interested in what is done to them as long as physical isolation is successfully maintained, and the standards of middle-class pity are applied. Third, although physical isolation is comparatively easy to achieve because it depends upon the known capacities of the human body (and also because a good percentage of inmates have no real intention of leaving), both rehabilitation and therapy remain problematic because so little is known about either. In prisons, especially, the inmate peer group has closer contact and control over the individual inmates than the staff either can develop or wishes

to develop, and these peer groups will resist the attempts of the staff to reform the inmates. Thus the relation between the staff and the inmates is reminiscent of the relations between the police and organized crime. The staff's administrative and rehabilitative policies will follow a combination of ideological and self-gratificatory lines. Colleges and universities are not very different in this respect.

**The prison as socializer.** Under the conditions described above, it is surprising that the recidivism rate of released prisoners oscillates between 30 and 40 per cent (Glaser 1964). True, some of this is accounted for by the ex-convict's better techniques for evading arrest, just as many of the patients who never return to the mental hospital have learned to be sick at home. And there is a certain percentage of prisoners (especially wife murderers and first-time embezzlers) who reject convict values and never intend to repeat their offenses (in American prison slang these prisoners are known as "square Johns"). Wheeler (1961) has shown that there seems to be a U-curve of conformity to social values on the part of the inmates who do not belong either to the class of "square Johns" or to that of "gorillas" (seasoned hoodlums). As the inmate nears release, he seems to make some attempt to reorient himself to the values of the outside world. As one would expect from Parsons' analysis of the ambivalence of deviant attitudes, a homogeneous and definitive deviant motivational structure is as rare as a homogeneous and definitive conforming motivational structure. Hence the desire and capacity of the convict to rejoin those who conform are greater than had been foreseen by the critics of the prison system.

The major obstacle to rehabilitation seems to lie in the transition from prison to the outside world. The difficulties center in two areas: (1) the fantasies about civilian life that are elaborated in the prison concerning jobs, income, and women insure that the ex-convict will be disappointed with conforming roles, especially since he can rarely secure one of the more attractive jobs immediately upon release; (2) the loss of primary group support that is involved in quitting the underworld to join the conforming community leaves the ex-convict without support while he is trying to break through the public stereotypes—although there is impressionistic evidence that the rejection he anticipates may be more of a problem than the rejection he experiences. The new trend in rehabilitation seeks to cope with these problems by creating "halfway houses" that facilitate and guide the ex-convict's return to society and offer him the support of a peer group composed of people who are in the same situation and who are trying to succeed in it. This

form of peer group support is lacking in traditional parole procedures. [See *PENOLGY*.]

The other way in which prison life may alter the motivation of the inmate, especially the young inmate, is to develop in him the personality attributes that are functional to the successful discharge of conforming roles. The ideals of the "right guy" (Sykes 1958) are those of self-control, self-reliance, avoidance of self-pity, not getting into trouble, and avoiding or minimizing involvement with homosexuality. For the young adults who make up the bulk of prison commitments, the capacity to internalize these attitudes would imply a capacity to resist delinquent peer group pressures and the impulses to aggressive acting out that often caused their incarceration in the first place. It is true that the result of modeling oneself after the "right guy" might be a deeper commitment to underworld values and—perhaps more important—to the underworld as a collectivity and to its role structure. But some of this commitment to underworld values might be, if one accepts Wheeler's U-curve theory, more conducive to adjustment than effective internalization would be. This is because commitment to the ideology of the convict group in the prison is more a flag of membership and a boundary maintainer against the authority structure than a real commitment to action on lines supported by this ideology. Accordingly, "prisonization" (that is, getting adjusted to the conditions of prison life) is not the equivalent of criminalization (Glaser 1964). For those who internalize both the underworld value system and the behavioral skills symbolized by the concept of the "right guy," the changes in personality structure may well result in a better adjustment to the outside world through a greater conformity to its basic rules of behavior.

**The fringe organization.** An organization that promotes policies sharply at variance with the political, religious, or moral principles of the society, or that imply at least a drastic change in the hierarchy of social values, may properly be called a fringe organization. The concept is a development of Parsons' "secondary institution."

The fringe organization claims a special relation to the dominant values even though, in fact, it deviates from the established norms and role expectations. It tends to attract deviants whose field of deviance may be quite remote from the overt goals of the organization. What the deviant finds in his membership is a re-evaluation of his personality. He can now reject the outside rejecters. His superego pains are lifted and transformed into anxiety to do well in his new group. [See *SOCIAL MOVEMENTS*.]

As the member achieves good standing in the

fringe organization, he is granted esteem, and this consolidates his learning. However, the support and esteem that legitimate the member's ego in his own eyes also increase the legitimacy for him of those needs of his which are not integrated with the fringe organization's role structure. Soon the member learns dissent. He discovers the discrepancy between the group's utopian values and its organizational limits. He comes to realize that the out-groupers are neither better nor worse than the in-groupers. His growing participation in activities involving out-group members (for the adolescent and young adult these activities are often love affairs) increases his resistance to the fringe organization's attempt to monopolize the whole of his life. Soon he is ready to leave the organization and rejoin the wider community. His experience in the fringe organization has served as a therapeutic experience that permitted him to work out pre-Oedipal, Oedipal, or post-Oedipal problems that formerly made it difficult for him to assume his regular age, sex, and status roles.

The fringe organization thus serves society as a resocialization agency. But its services must be publicly unrecognized if it is to remain effective. Harassment by the conforming world is an asset to the fringe organization, which therefore engages in activities capable of triggering sufficient harassment to warrant feelings of martyrdom and hostility but not sufficient to end in the destruction of the group. Hence, the group must plan its deviance as a combined effort. This makes its protest more effective but at the same time compels it to follow the norms of intergroup conflict that are proper to the society at large. Thus the fringe organization becomes in some ways more dangerous to society and in other ways more reasonable and more predictable than would be the many unpredictable role failures of its members if the latter were let loose upon the world as random individuals.

Behind the screen that the police and public interpose between the fringe organization and the rest of society lies a deviant social system that might even represent an institutionalization of a higher level of value commitment, and so prove itself superior to the existing social system. For a society can be wrong in terms of its objective possibilities; the deviant may be right, and the better often begins as the enemy of the good. More often than not, however, the fringe organization will be merely a group that enrolls the emotionally handicapped under the flag of utopia. Yet it may also be a group that, like the first Christian sect, may teach the world a way to live in society with less bloodshed, less violence, less contempt. By tolerating the

existence of the fringe organization, society leaves the way open for its own renewal.

Social control, as a specific topic for sociology, seems to be less popular now than in the past, when it was closely related to a concept of the source of deviance as being essentially located in the individual. But as the source of deviance has come to be located in the contradictions of the social system, the idea of controlling deviant individuals has become somewhat repugnant, and social reform itself has begun to look more than a little naive to a sociology penetrated with the knowledge that deliberate change always has unanticipated consequences.

Social control was once a concept which covered many areas that later became independent specialties—areas like penology, medical sociology, and the sociology of law. Even such large, amorphous areas as social change can be said to overlap with the area of social control. Hence there is now less interest in a topic which, if it is to be treated as something other than a summary of the various specialties, requires a level of theoretical generality that may seem beyond our present reach. However, it is possible that the concept has been neglected for two reasons which are rooted in the structural conditions of sociology as an intellectual enterprise. First, there is the fact that the study of social control would seem to require a combination of professional skills both in the sphere of individual psychology and in social system analysis. At any rate, such a combination will be necessary if we are to secure (1) a better understanding of the meaning of role participation for the economy of the personality (for instance, in the tension-inducing and tension-reducing role functions that may have a direct effect in promoting or decreasing deviant propensities); and (2) a better understanding of adult socialization patterns, so that we can ascertain the impact of social control agencies in fostering motivational changes that go beyond mere increased awareness of expediency [*see* SOCIALIZATION, *article on* ADULT SOCIALIZATION]. This would require, among other things, research into the life patterns not only of members of total and of fringe organizations but also of those who have left them, regardless of the costs of tracing them and of getting *reliable* indications of their conforming and nonconforming behavior.

The second structural handicap to the development of a theory of social control is the fact that it is an area which is rent with ideological debate. In particular, there is a struggle for the leadership of social control agencies between therapy-oriented

professionals and supporters of the classical judicial apparatus. Sociologists have sentimental and economic ties with the first group, and this makes it harder for them to maintain scientific detachment. Some, who feel more acutely the possibilities of conflict between their status group allegiance and their allegiance to objectivity, try to resolve the problem by flight from the field. Others will no doubt struggle on and let the facts speak for themselves.

## II

## ORGANIZATIONAL ASPECTS

All social units control their members, but the problem of control in organizations is especially acute. Organizations are social units which serve specific purposes. They review their own performances and restructure themselves. In this way they differ from natural social units such as the family, ethnic groups, or the community. The artificial structure of organizations and their concern with performance, as well as their tendency to be larger than natural units, make informal control insufficient and primary identification inadequate. Hence, organizations tend to require formally institutionalized allocation of rewards and penalties to enhance compliance with their norms, regulations, and orders. As a rule, organizations cannot rely on most of their participants to carry out assignments voluntarily. The participants need to be controlled.

For organizational means to fulfill their control function they have to be allocated differentially, so that performances desired by organizational norms will be rewarded while undesired performances will be punished. The allocation of means by the organization independently of performances, such as rewarding people for being white rather than Negro or male rather than female, does not directly enhance organizational control. Allocation according to such irrelevant criteria is more common in the less developed countries and is one of the reasons for the low effectiveness of organizational control in these countries.

The means of control used by an organization can be exhaustively classified into three analytic categories: physical, material, and symbolic. The use of a whip or a lock is physical in the sense that it affects the body; the threat to use physical means is viewed as physical because the effect on the subject is similar to that of the actual use. The

application of physical means for control purposes is here referred to as *coercive power*. Material rewards consist of goods and services; the granting of symbols (for instance, money) that allow one to acquire goods and services is classified as material because the effect on the recipient is similar to that of material means. The use of material means for control purposes is here referred to as *utilitarian power*. Symbols the use of which does not constitute a physical threat or a claim on material rewards should be viewed as pure symbols. These include normative symbols such as those of prestige and esteem and normative social symbols such as those of love and acceptance. (When physical contact is used to symbolize love or material objects to symbolize prestige, such symbols are viewed as normative because their effect on the recipient is similar to that of pure symbols.) The use of symbols for control purposes is here referred to as *normative* or *normative-social power*. Normative power is exercised by those in higher ranks to control the lower ranks directly; normative-social power is more commonly used indirectly—for instance, when the higher in rank use an individual's peer group to control him, as a teacher might do in a classroom.

The use of various classes of means for control purposes—power, in short—has different consequences in terms of the nature of the discipline elicited. All other things being equal, the use of coercive power, in most cultures at least, is more alienating to those subject to it than is the use of utilitarian power, and the use of utilitarian power is more alienating than the use of normative power. Or, to put it the other way around, normative power tends to generate more commitment than utilitarian power, and utilitarian power more commitment than coercive power. The application of symbolic means of control tends to persuade people, that of material means tends to build up their self-oriented interest in conforming, and that of physical means forces them to comply.

Most organizations most of the time use more than one kind of power. The kinds of power used vary according to the ranks of the participants to be controlled. Organizations tend to apply the less alienating means of control to their higher participants. Coercive power is as a rule applied only to lower participants: inmates are locked up if they try to escape. Higher participants are more often rewarded materially in order to increase their performances. It is therefore essential, for sociological purposes, to compare participants of the same rank in different kinds of organizations or of different ranks within the same organization. Otherwise one

## SOCIAL INTEGRATION

See under INTEGRATION.

## SOCIAL MOBILITY

Social mobility is the movement of individuals, families, and groups from one social position to another. The *theory of social mobility* attempts to account for the frequencies with which these movements occur.

The study of social mobility relates a present to a past social position. It thus forms part of the more general study of *social selection*, i.e., of how people get distributed into different social positions. It is, however, hardly possible to study effectively the influence of past social position except in the context of other influences that determine the in-

dividual's present social status. In practice, it has become increasingly difficult to separate the fields of social mobility and social selection. No rigorous separation has been attempted in the following discussion.

Studies of *intergenerational mobility* compare the social positions of parent and offspring; studies of *career mobility* compare the social positions of the same individual at different times. *Group mobility* is concerned with changes in the social position of groups possessing a relatively homogeneous status (for example, castes, intellectuals, artisans).

In the context of mobility studies, *social position*, or *social status*, signifies a certain rank with respect to the possession of goods (values) esteemed and desired by most members of a society. The changes in social position that interest the theory of social mobility are primarily variations in occupation, prestige, income, wealth, power, and social class. A high or low rank in one of these values is often associated with a roughly corresponding rank in most of the other values; consequently, position with respect to one of these values, and more especially a constellation of them, provides a measure of what in many societies is viewed as success in life. Studies in social mobility do not usually concern themselves with the possession of aesthetic, moral, and spiritual values. This is presumably due to the supposition, correct for most societies, that these goods do not measure "success in life." Nor does their possession seem to lead, except in a limited number of societies, to the attainment of those material goods whose pursuit is more evident in human behavior and whose possession tends to limit the amount possessed by others and to provide opportunities for—or at least the illusion of—control over one's own and others' destinies.

### Mobility and moral critiques of society

Political and moral critiques of society have both inspired and been inspired by studies in social and, more particularly, intergenerational mobility. This is understandable in view of the concern of intergenerational studies to show the relation of an individual's life chances (income, occupation, prestige, etc.) to the social circumstances (parental status) in which he is brought up. Casual observation, historical studies, and quantitative inquiry have long made it evident that despite considerable intergenerational movement up and down the social ladder, many children of high-status and low-status parents retain, when adults, approximately the same status levels as their parents. Egalitarian sentiments are affronted by a social process that appears to condemn many children to the inferior life cir-

cumstances of their families or to guarantee to other children, by virtue of the more favored position of their families, a high degree of fortune. Observation of these continuities in family social position has led to the characterization of societies as "open" or "closed" according to the degree to which the adult status of offspring is independent of (*open society*), or dependent on (*closed society*), the social status of the parents.

Independence is sometimes interpreted, in this context, in its strictly statistical sense: societies are egalitarian (open, democratic) to the extent that children coming from very different family backgrounds have the same probability of achieving a specified status level. This criterion, however, could be met without any commonly accepted view of social justice being fulfilled. This distribution of social positions might equally well be achieved were children assigned to occupations or income levels by a state lottery or by a purely whimsical procedure of an absolute ruler.

Societies are also sometimes viewed as being more or less open according to the frequency with which social mobility occurs. This criterion is not consistent with the criterion of statistical independence. The maximum frequency of social mobility occurs (for example, in a two-status system) when all the children of high-status parents fall to low status and all children of low-status parents achieve high status. This entails certain consequences of dubious accord with commonly accepted notions of social equity: offspring of low-status parents must resign themselves to seeing *their* children excluded from high status; and the future social position of children is as fully fixed by that of their parents as in the most rigid caste society.

Evidently, moral and political critiques of society must rest not on distributions of children's status by parents' status (see Tables 1-4) but on the nature of the processes that produce these distributions. Late eighteenth-century and nineteenth-century writers on these problems were concerned in their critiques of society with the institutional and personal factors involved in mobility; they aspired toward a society in which merit and talent were rewarded and opportunities for their development and exercise were freely available. Contemporary writers have by no means abandoned this theme; but with the increased availability of quantitative data they have been more disposed to substitute summary statistical indices of the frequency of mobility for critical analysis of the total process of social selection. This seems to assume either that certain frequencies are in themselves desirable without regard to the institutional and personal

factors involved in social selection or that the frequency of mobility in itself provides secure knowledge concerning the nature and moral legitimacy of the selection system. Neither of these assumptions appears justified.

### The mobility table

A central feature of most quantitative studies of intergenerational mobility is the mobility table (see Tables 1-4). An understanding of the technical problems associated with it is essential to the interpretation of the large body of data such tables have made available.

**The mobility scale.** If no additional assumptions are made, the social positions (e.g., occupations) between which movement may occur remain a series of discrete, qualitatively different categories. The study of social mobility is, however, closely related to questions concerning social achievement and, more particularly, concerning the role of the parental social position in determining filial status. Interest attaches, then, to the amount of *upward* and *downward* mobility (or conversely, the amount of nonmovement, or *inheritance*). The terms "upward" and "downward" imply an *ordering* of the categories along some quantitatively defined axis. When the social positions are defined in terms of (occupational) prestige or income level, an ordering is more readily made, although in the first case not without difficulty. Often, however, the social position categories represent occupational classes (professional, entrepreneurial, clerical, skilled, etc.) or social classes (upper, middle, lower) arrived at, not by one clear-cut criterion (e.g., income, education), but by a mixture of criteria that often leaves the meaning of ordering on a *single* axis, and hence the interpretation of the data, in doubt. The difficulty is not entirely resolved by reducing the multiple criteria to a single score, since a considerable measure of arbitrariness enters into the weight assigned to each criterion in the total score.

Even if a satisfactory ordering is achieved, the categories may not mean—and in the empirical literature generally have not meant—that the social positions represent *scale* positions. It is, therefore, not always possible to say whether movement ("distance") from social position A to social position B is as great as, greater than, or less than, movement from B to C. Recourse is sometimes had to speaking of the number of "steps" (ordered classes) through which movement has occurred. Clearly, however, these steps do not necessarily have the same significance, and this creates difficulties in relating the probability of movement be-

tween two positions to the "distance" separating them.

**Mobility and number of social categories.** A fundamental datum of the mobility table, the proportion of sons who manifest upward or downward mobility (or conversely, inheritance of the parental position), can be made larger or smaller by a simple change in the number of occupational or other classes representing the range of social positions. Thus, the amount of mobility (or inheritance) that a mobility table reveals is dependent on how fine (or broad) the social position categories are—a point that requires particular attention when inter-society comparisons are being made. The tendency toward arbitrariness in the number of occupational or other classes employed is increased both by the practical necessities of research (data availability, manageability) and by the use of multiple criteria in constructing the social-position classes.

**Mobility within the life-span.** Social position often varies during the life-span of the individual. It would, therefore, be desirable to make comparisons of the social position of father and son at several time points during their careers. This would also throw light on career mobility and bring its investigation into closer relation to intergenerational studies. Practical difficulties, especially in the specification of the father's status at several time points, have generally discouraged the use of this procedure. If only a single time point in each career is used to fix the social position of the father and his son, a choice must be made appropriate to the objectives of the study.

When the aim is simply to measure the frequency with which sons attain a higher, lower, or similar status to that of their fathers, it is reasonable to match their occupations at corresponding ages, preferably a fairly mature age, when the occupational career has become relatively stable. Other choices are to compare the highest status levels achieved in each generation and to compare the occupations pursued over the longest number of years.

On the other hand, when analysis is directed toward understanding why the son attains the particular status that distinguishes his position, quite different considerations enter. The question is then which point in the parental occupational career best aids in the prediction of the filial status. Consequently, the investigator must choose a hypothesis to be tested; the question of comparability in the ages of father and son is not involved.

**Sampling problems of father-son studies.** Intergenerational mobility tables are usually constructed by obtaining from a sample of subjects (sons)

their occupations and those of their fathers. But the probability of major interest is the probability that a son will attain a certain status given that the parent has a certain status. From this standpoint, and some others, it would be preferable to select a sample of fathers and trace the occupations of *all* of their sons, since the desired probability (when calculated from a table based on a sample of sons) is subject to error. This procedure is generally avoided because of the considerable age the fathers would have had to attain in order to ensure that the sons have likewise attained a fairly mature age and stable occupation. In addition, the fathers who have survived to that age would be a biased sample of the fathers of the current generation.

**Adjusting for size of occupation.** The mobility table provides an estimate of the relative frequency with which the sons of any particular class of fathers will be found in their fathers' occupation (inheritance) or in an occupation of higher or lower status (mobility). However, the entries in the mobility table reflect not only the effect of the father's status on the son's occupational locus but also the effect of the size of each occupational group. The probability that the son of a cabinet-maker will also become a cabinetmaker is a function not only of the special advantages and motivations that may accrue to him from the nature of the paternal occupation (and family circumstances correlated with it) but also of the number of cabinetmakers that the society requires or supports. It is often desirable, then, to separate the component of mobility that is due to the current occupational distribution from the component that reflects the influence of the parental status. One way of effecting this separation is to relate the probability of movement from position  $E_j$  to position  $E_k$  to the number of positions at  $E_k$  currently available in the society.

The original entries, in percentage form, are the probability that a son will be in class  $E_k$  given that the father is in class  $E_j$ , written

$$P(E_k|E_j) = \frac{\text{sons, with fathers in } E_j, \text{ who enter } E_k}{\text{all sons with fathers in } E_j}.$$

This expression is then divided by the proportion,  $P(E_k)$ , of all sons who have entered occupation  $E_k$ , which gives

$$M_{jk} = \frac{P(E_k|E_j)}{P(E_k)}$$

where  $M_{jk}$ , the mobility ratio, is the transformed entry that expresses the amount of movement (or in the diagonal cells, inheritance) from  $E_j$  to  $E_k$  relative to the number of "openings" at  $E_k$  in the society (see Tables 1 and 2).

Adjustment for occupational birth rate. The chances of movement into a particular occupation are also affected by differences in the birth rate of the various occupational classes. If, for instance, doctors had very few children, then, assuming a constant size of the medical profession, the medical replacements of the next generation will tend to come more largely from the children of other occupational groups.

The effects on mobility of the occupational distribution and of differential occupational birth rates are sometimes termed *structural components* of intergenerational mobility. These are to be contrasted with the effect of parental status (and of factors correlated with it).

Interpreting mobility ratios. The calculation of  $M_{jk}$  provides a standard in terms of which mobility may be viewed as high or low. If sons were distributed in occupations on a purely random (chance) basis, then the sons of any given parental class would enter the various occupations simply in proportion to the size of that occupation in the society. In this case  $M_{jk}$  has the value of 1.0. A value of  $M_{jk}$  greater (or less) than 1.0 signifies that sons from a particular class of fathers are entering an occupation more (or less) frequently than would be expected on a purely chance basis. Thus, deviations of  $M_{jk}$  from 1.0 indicate the operation of factors associated with "father's status."

### Findings of intergenerational studies

Tables 1-4 provide illustrative intergenerational mobility findings. In Tables 1 and 2 the upper entries in each cell are percentages, and the lower, parenthetical entries are the cell values for  $M_{jk}$  (see above). These are summary tables and do not permit analysis in terms of particular age groups or

other demographic subdivisions. These and numerous other tables to be found in the literature suggest the following statements:

(1) Mobility tables uniformly show deviation from random distribution, that is, they show that filial status is statistically (and positively) dependent on parental status in varying degrees (see Tables 3 and 4). Impressive as this relationship may appear to casual inspection, it is equally apparent that the sons of most classes of fathers are distributed in substantial numbers throughout most of the status classes. Evidently, then, the status of the father permits considerable variation in the status of the son. A more precise summary statement of the over-all relationship suggested by the available studies is that probably not more than one-quarter of the variance in filial status is accounted for by parental status; and this includes the effect of some factors correlated with, but not properly included in, parental status (e.g., race).

(2) The sons are most heavily overrepresented (as compared with random expectation) in the diagonal cells, that is, in those cells representing inheritance or a continuity by the son of the parental status. This necessarily implies underrepresentation in some other cells. This underrepresentation is generally spread over a larger number of cells and is, therefore, less striking, except at times when the parental and filial statuses are in very marked contrast. It follows, then, that for those sons who enter an occupational class different from that of their fathers, *which* particular other occupational class will be entered is, generally, less dependent upon the paternal status.

(3) The above findings lend themselves to two rather different emphases. On the one hand, it is probably correct to say that only one-quarter or

Table 3 — Sons' occupational status by fathers' occupational status, Great Britain, 1949, percentage distribution

SONS' PRESENT STATUS CATEGORY	FATHERS' STATUS CATEGORY							Total

Source: Adapted from Glass 1954, p. 183.

less of the over-all variance in filial status is accounted for by parental status and that consequently other factors, taken collectively, play a more important role in determining the status of the son than does parental status. At the same time, it is possible to select particular cells and quite correctly emphasize the large deviations from random expectation in these cases: for example, the considerable excess representation in professional occupations of sons of professional fathers; or the considerable deficiency among professional workers of sons of unskilled workers.

(4) The probability that the sons of a particular class of fathers,  $E_f$ , will achieve a given status level,  $E_k$ , is inversely proportional to the status "distance" between social positions  $E_f$  and  $E_k$ . Since the status "distance" is itself a function of several variables, such as education and income, this summary formulation cloaks a number of more specific relations of interest (see below).

(5) Much discussion has been devoted in recent years to two questions: (a) whether the rate of mobility has changed during the last generation or two; and (b) whether European societies show a lower rate of mobility (a greater continuity of family status from generation to generation) than the United States. Despite the number of mobility studies now available, numerous difficulties with respect to their design and comparability preclude confident answers to the foregoing questions. The following statements are therefore *tentative*.

Studies of the United States and most Western industrial societies with increasing urban sectors and considerable provision for education show in the last two generations no substantial over-all change in the tendency of sons to inherit the father's occupational class, at least when these are rather broadly defined. The available data do not suffice unequivocally to detect smaller changes that may in fact have occurred. It is evident that the decline in agricultural employment and some

skilled crafts, and the emergence of new occupations, operate to reduce occupational inheritance. But such changes have not been confined to any one generation and therefore do not necessarily produce drastic alterations in the mobility pattern. This is particularly true when social position is defined in terms of occupational prestige. The new occupations may leave unaltered the relative frequency of different status levels in the society and the distribution of the labor force among them. The increased access to educational facilities and the growth of large-scale enterprises also suggest that the data should show a decreasing dependence of filial status on parental status; but it may well be that more limited access to education in earlier years was offset by the correspondingly weaker emphasis on formal educational requirements and a greater reliance on apprenticeship and learning "on the job."

The United States has often been viewed as a society in which individual effort and merit are rewarded more substantially than in European societies and where family background counts for less than elsewhere in the distribution of status positions. Available studies, on the other hand, show no striking differences between the amount of mobility in the United States and western European societies (compare Tables 1 and 2 with Tables 3 and 4). However, most international comparisons have, in the search for comparability, reduced the data of individual studies to a least common denominator which denudes them of much of their value, and it is dubious whether, even so, comparability has been achieved. Nonetheless, there is one characteristic of U.S. society, absent in any similar degree from European societies, that may account for the difference between common assumptions and research findings; namely, a large Negro population subject to severe handicaps in the selection process. The position of the Negro in U.S. society adds to the correlation between pa-

Table 4 — Sons' social status at age 30 by fathers' social status at age 30, Denmark, 1954

SONS' SOCIAL STATUS	FATHERS' SOCIAL STATUS					Total	
	(1) (Highest)	(2)	(3)	(4)	(5) (Lowest)	%	N
(1) (Highest)	41.9%	5.1%	2.1%	.9%	.6%	2.3	45

rental and filial status in the lower strata of the status hierarchy. When the upward mobility rate of unskilled white workers is considered separately, it is appreciably higher than the upward mobility rate for the total unskilled group. The assumption that the United States has higher mobility rates than European countries may, then, rest in part on a disregard of a sizable sector of the society.

Finally, if, as suggested above, parental status accounts at most for only one-quarter of the variance in the distribution of filial status, considerable differences could exist in the operation of different social-selection systems without necessitating correspondingly great differences in the specific effect of parental status.

### Determinants of social mobility

Although the mobility table has been the principal product of many mobility studies, it leaves unanswered many questions central to the theory of social selection and social mobility. The "variable" parental occupation or status embraces, or rather conceals, a host of more specific influences. Research on social mobility is now increasingly directed toward untangling the roles of these more specific variables and shows a corresponding decrease of interest in simply adding new mobility tables to those already available. Further, with respect to the question of how people get sorted into different occupations or status levels, the mobility table can provide at best only a very partial answer, that is, an answer in terms of the statistical dependence of filial status on parental status. But there are clearly many other factors that determine occupational and status selection.

**Father's occupation.** Parental occupation or status is related to the probability of filial entry into an occupation in two principal ways: (a) the father's occupational status may be correlated with a variety of filial attributes, such as education, intelligence, and race, that affect the son's occupational locus; (b) the parental occupational status may affect filial occupational locus more directly: the father's occupational experience may influence his son's occupational interests and may provide him with special knowledge, experience, incentives, and opportunities for access to it or other occupations.

**Educational level.** A substantial portion—substantial, relative to other variables—of the variation in status is accounted for by variations in educational level. Educational level is, of course, in considerable measure dependent upon the status level of parents. This dependence is lessened by increases in the society's investment in educational

facilities and the degree to which these make educational opportunities available without respect to social origin. To the extent that this occurs, the relation of education to status achievement is freed from an intermediate dependence on parental status. Sons of similar parental status show variations in educational levels, and the effect of these variations on status certainly cannot be ascribed to parental status. However, the extension of educational opportunities may at the same time reduce the correlation between status achievement and education. The more widespread a certain level of education becomes (for example, primary or secondary education), the less will variations in status, especially in the lower reaches of the status hierarchy, depend on variations in educational level—provided, of course, that increased access to education does not change the status significance of the occupational groups.

**Intelligence and mobility.** Part of the effect of education on status achievement is due to the correlation of education with intelligence. In the process of status selection, variations in intelligence operate to influence the achieved level of social status, both by leading to variations in educational level and (for persons of similar educational level) by facilitating the advancement of those of greater intelligence. Certain educational attainments have, however, become such decisive prerequisites for entry into many occupational positions that high intelligence without the added attainment of a corresponding education is unable to produce its full potential effect. Even were educational opportunities commensurate with intellectual capabilities, the correlation of intelligence with status achievement would be limited by the dependence of achievement on motivational and other personality characteristics. An equally important limitation is the fact that, except in a certain gross sense, intelligence is not an overriding criterion in occupational selection and advancement.

Intelligence as customarily measured depends in part, in its turn, on environmental circumstances. But the present state of investigation also leads one to conclude that, even as currently measured, intelligence has a major genetic component. Consequently, part of the dependence of filial on parental status is due to two sources of correlation between parental and filial intelligence—social and genetic.

Recent studies have been effective in demonstrating the existence of complex interactions between parental status, education, and intelligence and in establishing that each of these variables plays a significant role in determining filial status,

both independently and by mediating the influence of the others. But tested models do not now exist that enable one to state quantitatively the probable change in status ensuing from an increment in one of the variables (occurring at a specified stage of an individual's life), given the values of the other variables. The introduction of a genetic component of intelligence complicates the task of building such a model but at the same time appears indispensable if such models are to be used to derive a picture of the evolution of the mobility or social-selection system over time.

**Discrimination.** In some societies the existence of sizable racial or other groups subject to various modes of discrimination increases the dependence of filial status on parental status. The common obstacle shared by father and son tends to show up as a correlation between their status positions. Since status position as defined by mobility studies does not usually include the criterion of race, this necessarily inflates the degree of dependence of filial status on paternal status.

**Other social handicaps.** Relatively little attention has been paid in mobility studies to the role of special deficits that are not severe enough to exclude persons from the labor force and yet act as powerful handicaps to occupational achievement. High-grade mental deficiency, physical disabilities, chronic disease, mental disorders, alcoholism, etc., taken together, have a sufficiently high incidence and a sufficiently decided effect on occupational achievement to influence mobility tables. It is possible that a substantial part of the cases of extreme downward mobility can be accounted for in this way.

**A neglected source of downward mobility.** A further source of downward mobility may be viewed either as the result of a bias in the design of mobility studies or as an intrinsic feature of the parent-son status relationship. Mobility studies generally draw a sample of the gainfully occupied within the age range chosen for the investigation. The sample usually includes unmarried subjects and married subjects with and without children. The father sample, arrived at through the son sample, will, however, necessarily include only persons of the preceding generation who have at least one son and are therefore (in most cases) married. Since marriage and sometimes fertility are associated with greater occupational stability, mental and physical health, and general achievement, the fathers of the subjects will represent a special sample of their generation. If this is viewed as a bias in comparing the status of fathers and sons,

it could be overcome by choosing the subject (son) sample only from those in the labor force who are married and have at least one child. Since, however, all sons *must* come from the special (father) sample of the preceding generation, it is more useful to view the differential character of the father and son groups as one source of downward mobility. Given the biological and social significance of marriage and, perhaps, fertility, fathers are, other things being equal, superior as a group to an *unselected* sample of their sons. Consequently, one should expect that for this reason a number of the sons will arrive at status positions inferior to those of their fathers.

### How important is parental status?

The variables cited above account for a large measure of the filial status distribution. Does this mean then that the emphasis on the derivation of filial status from parental status has been misplaced? In part, the answer is certainly, Yes. But there is, nonetheless, a danger that the reduction of parental status to a series of more specific and often independently operating factors may lead to a neglect of those sources of influence in the parental occupational situation that exercise a direct influence on the son's occupational destiny by giving him special knowledge, incentives, and opportunities with respect to particular occupations. In dealing with sons who are professionals (or even more so, who are white-collar workers) it is fairly easy to account for their occupational status without making an appeal to the *specific* occupational locus of their parents. But if we are required to predict, not which sons will become professional or white-collar, but rather which sons will become doctors or cabinetmakers, then whether the parent is or is not a doctor or a cabinetmaker is still of considerable importance.

Behind the propensity of some classes of fathers to produce sons who follow in their occupational footsteps appear to lie certain relationships that, however, can be stated only very tentatively. Sons seem to be more likely to pursue their fathers' occupations under certain conditions: (1) if the fathers are self-employed; (2) if the self-employed fathers utilize a substantial capital in the pursuit of their self-employed occupations; (3) if entry into the father's occupation is regulated by licensing, examinations, union control, apprenticeship, or other obstacles that the parental status may aid the son to overcome; (4) if the parental occupation requires special training or education. Naturally, these relationships operate more effectively if the

occupation involved provides satisfactory rewards relative to alternatives open to the sons.

There are numerous other individual and family attributes that affect the probability that a child will attain a given status position. The number of children in the family and the birth order of a child may in some institutional settings be particularly important. The motivations and aspirations of young people in different sectors of society obviously play an important role in determining the manner in which various individual and family assets and handicaps exercise their influence.

### Social mobility and social structure

Finally, at least a brief word must be said about the relation of social selection and social mobility to the principal institutional structures of society. The research to which we owe the many mobility tables now available has been mostly pursued in Western industrialized societies with large urban sectors. This has made it easier to disregard the role of major institutional differences in the formation of social-selection systems. Current studies have tended to confine their attention more particularly to demographic and technological changes and to the role of educational institutions and the practices which affect access to them. Although there is a considerable literature on employment procedures, the study of social mobility has not adequately taken account of the fact that the occupational distribution process is a dual process, in which two sets of preferences and decisions, those of the employee and those of the employer or manager, confront each other, and that the distributive outcome is affected by the supply and demand of various qualities.

There are other major institutional features that, because of their relative stability, best reveal their relation to social mobility when it is studied over quite long time spans. Even the most stable political, juridical, and economic institutions of a society are of capital importance for the mobility process. Thus, the occupational selection process in Western society is decisively influenced by the nature of the labor contract, by laws relating to freedom of movement, and, ultimately, by the distribution of political power, together with the political and social sentiments associated with this distribution. As increasingly complex models of the social-selection process are developed, it will become necessary to specify more explicitly and exactly the institutional environment to which the model has application. Perhaps, too, it will become possible to relate parameter values to changes in

the institutional environment and thus to unify the interests of quantitative research and comparative historical inquiry.

## SOCIAL MOVEMENTS

The articles under this heading survey and analyze the general features of social movements and describe various approaches to their study. Specific movements and types of movements are discussed in ANARCHISM; CIVIL DISOBEDIENCE; COMMUNISM, article on THE INTERNATIONAL MOVEMENT; CONSERVATION; FALANGISM; FASCISM; IMPERIALISM; LATIN AMERICAN POLITICAL MOVEMENTS; MILITARISM; MILLENARISM; NATIONAL SOCIALISM; NATIONALISM; NATIVISM AND REVIVALISM; PACIFISM; PAN MOVEMENTS; SOCIALISM; SYNDICALISM; ZIONISM. Related modes of organization are discussed in INTEREST GROUPS; PARTIES, POLITICAL; SECTS AND CULTS; VOLUNTARY ASSOCIATIONS; and in many of the articles listed in the guide under RELIGION. For the relationship of social movements to ideology, see IDEOLOGY; INTERNATIONAL RELATIONS, article on IDEOLOGICAL ASPECTS; RADICALISM; REVOLUTION; UTOPIANISM. The impact of social movements on the social structure is reviewed in COLLECTIVE BEHAVIOR; MASS PHENOMENA; MASS SOCIETY; ORGANIZATIONS, article on ORGANIZATIONAL GOALS; POLITICAL SOCIOLOGY.

- I. TYPES AND FUNCTIONS OF SOCIAL MOVEMENTS
- II. THE STUDY OF SOCIAL MOVEMENTS

Rudolf Heberle

Joseph R. Gusfield

### I

#### TYPES AND FUNCTIONS OF SOCIAL MOVEMENTS

The term "social movement" or its equivalent in other Western languages is being used to denote a wide variety of collective attempts to bring about a change in certain social institutions or to create

an entirely new order. Sometimes the term is used in distinction from *religious* or *political* movements and from movements among particular groups, for example, the women's movement or the youth movement. As all of these movements occur in society and tend to affect, directly or indirectly, the social order, it would be permissible to apply the term social movement to all of them. However, when the term first came into use, early in the nineteenth century, it had a more specific meaning: the social movement meant the movement of the new industrial working class, with its socialistic, communistic, and anarchistic tendencies. A German scholar, Lorenz von Stein, was one of the first to recognize that the real political significance of socialism and communism lay not in their value as forms of social thought but in the fact that they gave expression and direction to the strivings of the industrial proletariat toward a new social order which would abolish economic exploitation and give the workers a chance to achieve full personality development.

On the continent of Europe, the identification of the social movement with the labor movement lasted until the second decade of this century. Today this narrow definition of the concept is no longer possible in view of peasants' and farmers' movements, of Fascism and National Socialism, and of the independence movements in colonial countries—to name only the most important instances.

It is advisable, however, to distinguish between movements which, because of their limited goals, never attract more than small groups of people and those which, aiming at comprehensive and fundamental changes in the social order, become true mass movements of historical significance. The latter will be referred to as social movements in the strict or "classical" sense. The former are sometimes referred to as "protest movements," but this term may also be used to designate mass movements which seek to redress grievances of certain groups (for example, the Negro movement) as well as movements opposing social (or political) change (for example, the Ku Klux Klan or the White Citizens' Councils in the southern United States).

Although it is sometimes convenient to distinguish between social and political movements, it should be noted that *all* movements have political implications even if their members do not strive at political power.

Social movements are a specific kind of concerted-action groups; they last longer and are more integrated than mobs, masses, and crowds and

yet are not organized like political clubs and other associations. A social movement may, however, be comprised of organized groups without having one over-all formal organization (for example, the labor movement, which comprises trade unions, political parties, consumer cooperatives, and many other organizations). Group consciousness, that is, a sense of belonging and of solidarity among the members of a group, is essential for a social movement, although empirically it occurs in various degrees. This consciousness is generated through active participation and may assume various sociopsychological characteristics. By this criterion social movements are distinguished from "social trends," which are often referred to as movements and are the result of similar but uncoordinated actions of many individuals (for example, the suburban movement, fads, and fashions).

The classical concept of social movement implies the creation of an entirely new socioeconomic and political order, especially as concerns the institutions of property and the distribution of power. To justify these aims, all major social movements develop a more or less elaborate, more or less consistent set of ideas which its members must accept more or less uncritically, as members of a religious group would accept a creed. From these "ideologies," or "constitutive ideas," are derived "action programs" of a more changing nature. Social movements tend to spread beyond the boundaries of states or national societies and to extend over the entire area of a civilization, or even beyond, as far as the social order that is their target reaches.

"Protest movements," as the term is used in this discussion, are, as a rule, limited in spatial expansion, being mostly of local, regional, or national character, for example, many "radical" farmers' and peasants' movements. A formally organized protest movement represents one kind of "pressure group." Transformation of a protest movement into a genuine social movement is possible; the early labor movement showed many traits of a protest movement, and labor unions often act as pressure groups. Neither protest movements nor pressure groups develop, as a rule, a comprehensive political action program or an elaborate ideology. While the relations between social movements and political parties will be discussed later, it should be pointed out that political parties are not necessarily differentiated by ideologies.

In spite of their different and often antagonistic aims and ideologies, certain social movements show similarities in structure, tactics, and other

formal aspects, while other movements, although similar in their ideologies, are significantly different in other respects. While the earlier studies of social movements have concentrated on the ideas, more recent sociological research has given equal attention to the structural and psychological aspects.

### Ideas

Movements aiming consciously at a radically different social order, a "change from the roots," are possible only when the social order is seen not as a divine creation but as a work of man, subject to man's will. Movements of this kind are concomitant with the secularization of thought. This is why such movements have occurred in the West only since the eighteenth century and in the East quite recently as a consequence of cultural contact with the West. Earlier revolts and disturbances among the lower social strata typically aimed at improving their social position without attacking the social order in its foundations. Radical movements in the earlier periods tended to assume the character of millenarian religious or quasi-religious sects. Similar movements still occur in regions where the transition to modern society is lagging. These movements were, as a rule, defeated unless they adopted the organization, tactics, and ideology of modern movements.

In the attempt to justify their aims, modern social movements typically resort to abstract principles concerning the nature of man, his destination, and his natural rights in combination with a critique of the existing economic, political, and cultural institutions. The ideas of liberty and equality are common to all major social movements, sometimes in combination with the idea of national unity and independence.

The most typical forms which the philosophy of a movement assumes are either a detailed, rational plan for a new society—a utopia—or, as in the case of Marxism, a theory of history which predicts the inevitable coming of the new society without revealing its form in detail. Characteristic of these thought systems is their inherent logical consistency, their reliance on monocausal explanations of major social problems, and their tendency to believe that changes in social institutions will bring final solutions to all human problems.

The defenders of the existing order will create counterarguments, which become the constitutive ideas (or ideology in the narrow sense) of a countermovement. Typically, these countermovements incorporate some of the ideas of their adversaries but otherwise use any argument that may serve

in defense of their position, regardless of resulting logical contradictions. Some have made effective use of symbols (the Third Reich) in order to achieve solidarity among adherents. Either type of belief system may be regarded as an expression of the collective will of the social groups in which they are developed and accepted.

While the methods of analyzing belief systems of social movements have been refined by the "sociology of knowledge," it is important to recognize the element of *volition* in the ideologies, since this is what makes them socially effective. The belief in a set of constitutive ideas binds the members of a movement together and gives them the *élan* needed for the persistent pursuit of the movement's aim. In some cases this belief can assume quasi-religious forms. If this happens, not only the ideas of antagonists but also any deviation from the orthodox ideology are branded as a heresy. [See IDEOLOGY.]

### Social-psychological characteristics

The motivations of individuals in joining a social movement may range from rational belief in the movement's aim (value-rational orientation) to pure opportunism. Quite often the decision to join is more emotional than rational—for example, when a person is "converted" by some experience which arouses his sense of justice—and in certain types of movements the mass of supporters are attracted by the personal charm of a leader rather than oriented toward an elaborate belief system or a definite action program (emotional-affectual orientation). When a movement has existed for a long time, it may, in certain families or occupational groups or local communities, become traditional to belong, as in the case of traditional socialistic orientation in many European working-class families. The example set by kinsmen, neighbors, or friends may give the incentive to join. [See PERSONALITY, POLITICAL.]

One can distinguish the following sociopsychological types of movements according to the prevailing motivation of their members:

(1) The value-rational "spiritual community" or "fellowship" of believers in the truth of the constitutive ideas and in the practical aims of a movement.

(2) The emotional-affectual "following" of a charismatic leader.

(3) The purposive-rational or utilitarian association for the pursuit of individual interests.

Combinations of these types are frequent, and transitions from one type to another may occur during the life cycle of a movement. What started

as a community of believers in a "cause" may develop into a "band wagon," attracting socially or politically ambitious opportunists. In some revolutionary movements the devotion to the cause becomes paramount to the degree that personal friendship and love among members and all personal, intimate relations with outsiders are discouraged—a paradox in movements which aim at the establishment of a more human, more fraternal order of society. Of course, reasons of security against police spies and traitors may contribute to these practices. On the other hand, there are cases where kinship and personal friendship contributed to the solidarity of members of a revolutionary movement.

The nature of a movement may also change as a new generation grows into it. By political generation we mean those persons of approximately equal chronological age who experienced the same crucial social and political events during the formative period of their lives, that is, roughly in their late teens and early twenties. The implication is that these experiences, among other factors, contributed to the formation of their social and political outlook on life (*Weltanschauung*). Although this concept presents serious difficulties to "operational definition," it is a most useful tool in understanding the origin and development and internal tensions and changes of social movements. [See GENERATIONS.]

Many attempts have been made to explain the origin and growth of social movements by relying only on psychic factors. These attempts have in many instances led to an overemphasis on non-rational motivations, even on pathological traits of founders and leaders as well as of followers, and have neglected the situational conditions out of which movements arise. While many early leaders of radical movements have been maladjusted personalities and while frustrated individuals are often attracted by such movements, mass adherence is gained by rational reaction to economic or other social conditions which are felt to be intolerable. Likewise, the popular notion that movements are generated by outside agitators has to be discarded; outsiders certainly accelerate the spread of a movement, but unless the local people are "ready," the agitator is likely to preach to deaf ears—or even be forced to leave.

### Organization and structure

Although social movements are by definition not corporate bodies, as action groups they need some kind of organization that enables certain persons to act as authorized spokesmen and representa-

tives. This can take the form of committees, clubs, labor unions, or political parties.

The relationship to political parties is of special importance. It may be of various patterns: (a) the party may serve as the political spearhead of the movement; (b) the movement may be represented in or exert influence through several parties; (c) a party may contain several movements—or parts of them; or (d) the movement rejects connection with any political party. Examples of (a) are the British Labour party in its earlier days and the National Socialist German Workers party (NSDAP) in relation to the broader Nazi movement; of (b) the labor movement in West Germany represented in the Social Democratic party (SPD) and the Christian Democratic Union (CDU); of (c) the major American parties; of (d) the Industrial Workers of the World (IWW) in the United States and anarchosyndicalism in general.

Political party by definition presupposes the existence of at least one other party within the body politic. However, the ideological parties which developed out of the communist and fascist movements (and some independence movements) aim at a monopoly of power and do not recognize other parties as legitimate adversaries or competitors. Since they are selective in membership and demand absolute obedience from all members, they are properly referred to as "political orders" rather than parties. These totalitarian parties aim at controlling all phases of social life through numerous affiliated organizations. [See PARTIES, POLITICAL.]

Affiliated organizations were, however, first devised by the social-democratic parties of continental Europe and later used by nearly all other parties. The primary purpose of creating women's, children's, and youth organizations together with educational, athletic, and a variety of other special-interest associations was not total control, as in the totalitarian orders, but recruiting new members and winning elections. Yet before 1933 a German socialist's life "from the cradle to the grave" could be spent in party-affiliated organizations. This indicates that for its adherents the party was more than a political institution; it was part of the broader movement in which the masses of industrial workers had found a "home"—a community of mind and spirit. The establishment of paramilitary forces by the fascist and National Socialist movements induced their opponents to follow their example.

The relations between the various organized groups constituting a movement are not always free of tension. For example, in some European countries the affiliation of trade unions with a po-

litical party has at times aroused opposition among those workers who did not share the political (socialistic) orientation of their union.

The growth of affiliated organizations together with universal franchise created problems of administration which could no longer be solved solely by reliance on part-time volunteer workers. Thus, large staffs of paid full-time workers developed in parties as well as in labor unions and other organizations within the major movements. While increasing the efficiency of the interior workings, the unwanted consequence of professionalization of the staff is often a decline in militancy. Persons who are responsible for a large organization on which people depend, will, in a critical situation, be reluctant to risk not only the lives of members but also the very existence of the organization and, eventually, its achievements. (This explains in part why the German socialist trade union leadership failed to resist Hitler in the spring of 1933.)

The power structure of social movements varies from diffusion of power to concentration of authority at the top level. Supreme authority may be institutional, that is, derived from the office to which a person has been promoted by legal procedure, or it may be charismatic, that is, derived from the belief in the extraordinary, quasi-superhuman powers of a particular person who, in turn, is motivated by the belief in his singular gifts, his call to leadership, and his political "mission." The founders and early leaders of social movements often come close to this type. However, genuine charisma is not to be confused with popularity of a leader.

In the fascist and Nazi movements, charismatic leadership was accepted as a principle and developed with all its characteristics and consequences, while Marxism-Leninism rejects the "cult of personality." This difference, obscured by labeling communist and fascist regimes as "dictatorships," is important for an adequate understanding of the structure of the two kinds of movements and of the resulting regimes. In particular, the problem of succession, which is critical in the case of charismatic leadership, is much less serious in the communist parties and regimes. [See CHARISMA; LEADERSHIP; TOTALITARIANISM.]

### Strategy and tactics

In politics, the distinction between strategy and tactics cannot be so sharply drawn as in the theory of war, but it is nevertheless important. In societies where freedom of opinion is granted, it is usually over tactics rather than strategy that a social movement will get into conflict with the government, especially if members of the social

movement engage in "direct action" (for example, sabotage, general strike, boycott, "sit-in," terror and violence) or in serious preparations for a *coup d'état*. Schisms in a social movement occur more frequently about tactics (for example, over the question of reform or revolution) than about strategy, although the more serious splits are usually those over long-range strategy (for example, the Stalinist-Trotskyite controversy). For the outsider, it is often difficult to decide whether a change in the policy of a movement is due to a change in final objectives or merely a tactical maneuver (this has been a major problem in dealing with communism).

Direct action, essentially undemocratic because it denies the opponent the chance to discuss the issue, is often resorted to when legitimate political action fails. In extreme situations the movement will culminate in a violent revolution.

The tactics and strategy of a social movement are interdependent with its ideology and its form of organization; for example, a movement aiming at revolution needs a more authoritarian organization than a movement believing in gradual reform. The choice of tactics as well as of forms of organization is in part dependent on the political system within which the movement operates and in part on the size of the movement and its influence within the political system. Therefore, the tactics of a social movement may change as it grows—they may become less revolutionary as the movement gains in influence, or they may become more aggressive as the chances of success increase.

Most social movements operate in public because publicity gives influence and increases adherence. However, secrecy is resorted to in situations where the rights of association, of assembly, and of freedom of opinion are denied or where members of a particular movement are subject to special prohibitive legislation and to persecution. The labor movement in its early phases was largely forced to secrecy. The consequence was—as it has been in similar cases—the splitting up of the larger movement into many more or less conspiratorial sect-like groups.

In political as in military action and in business, success comes to the innovator. The rise to power and the foreign-policy achievements of the Fascists and Nazis were, in part, due to the fact that they did not play according to the rules, while their antagonists at home and abroad expected them to. The same may be said, with modifications, of the communist movement: frequent tactical changes tend to confuse the adversaries. Mao Tse-tung succeeded because he deviated from orthodox Leninist strategy and tactics.

Radical revolutionary and counterrevolutionary movements are capable of violating the "rules of the game" because their members do not regard their opponents as part of the political community; they conceive of all politics in terms of friend-foe relations, where no holds are barred. This explains the use of terror before and after the seizure of power and the paradox that men who intend to create a better world for man are capable of sacrificing millions of human beings in the process.

### Class and ethnic movements

Two kinds of social movements have been of historical importance in recent times: class movements and movements of ethnic groups.

Examples of class movements are those of the middle class versus the nobility, peasants versus landlords workers against employers, farmers against middlemen, petty bourgeoisie against big business, and, more vaguely speaking, the poor against the rich. The supporting classes are typically those which, while gaining in economic significance and general socioeconomic achievements, feel economically exploited and politically suppressed. Some movements, particularly counter-movements and protest movements, originate among members of classes which are declining in socioeconomic significance. Thus, the European labor movement started among craftsmen who resented the loss of economic independence and among skilled industrial workers who represented the economic and intellectual elite of the proletariat.

A distinction should be made between peasant movements and farmers' movements. The former occur in societies where land is the property of ruling classes, who are not necessarily engaged in agriculture but who draw rent or other income in cash, or in kind, or in services from the peasants. The typical peasant movement aims at abolition of these obligations and the return of the land to its alleged or real original owners. Where peasants and landlords belong to different ethnic groups, for example, in some Latin American and in many colonial countries, the conflict is particularly sharp.

By way of contrast, modern farmers' movements occur typically among commercial farmers, especially in one-crop areas, where a high degree of economic insecurity exists. Unless there is a broad class of tenant farmers, the land question does not arise; the issues are mainly prices, interest rates, and taxes, and the main "targets" are the merchants, creditors, and the government.

Farmers' movements as a rule do not develop elaborate ideologies but raise concrete demands;

in this respect they come close to being mere protest movements. However, if their grievances are not alleviated, even modern farmers become susceptible to radical ideological movements (for example, German farmers during the rise of Nazism, French farmers and Poujadism). Peasant movements are likely to resort to violence. Their ideology, if one exists, may at the same time be traditionalistic and restorative. However, it is precisely in traditional areas of peasant unrest that contemporary communism has gained widespread support, especially in southern Europe and Latin America.

To say that a movement is supported by a given class does not mean that every member of the movement belongs to that particular class or that every member of the class belongs to the movement. These correlations are never perfect. Some movements are recruited mainly from uprooted or alienated members of certain classes (for example, most of the early Nazis, including Hitler, were *déclassé* lower-middle-class people). The founders, the leaders, and the framers of the belief system in class movements are often alienated members of another class.

Of particular importance in this respect is the role of the intelligentsia in furnishing leaders of revolutionary movements. Having no firm roots in their society, these men and women are susceptible to ideological beliefs which promise them a society in which their kind would find a satisfactory status.

The term "ethnic-group movement" is used to designate a variety of phenomena. The most important are (1) the movements for political independence of national minorities within the old empire states in Europe, (2) the independence movements of natives in colonial countries of Asia and Africa, (3) the movements for national unity—for example, in Germany and Italy in the nineteenth century and the Pan-Arabic movement in the twentieth century, (4) the movements of nationalities for civic and cultural equality within ethnically heterogeneous states (the Flemings in Belgium) and for superiority (the Finns in Finland).

As a rule these movements are led and supported primarily by the cultural, economic, and, in some cases, military elites who have vital interests in the attainment of the objectives.

The leaders of present-day independence movements in colonial countries are, with few exceptions, intellectuals and professional people, "marginal men" who have been subjected to Western culture and education. Their followers come by no means only or even in the first place from the lower social strata but, on the contrary and to a

large extent, from the recently developed classes of white-collar workers, civil servants, and military officers, as well as from the small and medium-sized businessmen, who find themselves handicapped by Western colonial rule and economic dominance. Additional support comes in many areas from miners, peasants, plantation laborers, and other categories of workers who have been in contact with Western systems of economy and government and who have been uprooted from the community of village or tribe. Even among primitive islanders in the south Pacific, movements have developed which are partly directed toward freedom from white dominance and are partly nourished by chiliastic expectations of enrichment through civilization, for example, the "cargo" cults [see NATIVISM AND REVIVALISM].

The Negro movement in the United States does not correspond to the typical pattern of ethnic-group movements because most Negroes do not aspire to political independence or cultural autonomy but to integration into American society and culture. Since the American Negroes are neither a national minority nor a social class, their movement does not aim at fundamental changes in the social order but rather at the realization of constitutional rights. However, achievement of the Negroes' aims would change not only local and regional customs but also certain parts of the existing legal order. The movement, therefore, is regarded by friend and foe as a "revolution." In its aims and tactics the Negro movement resembles the women's (suffragettes') movement. Like the early labor movement, it has received significant aid and leadership from outsiders.

In many instances one can observe that certain areas or regions of a country are the breeding places and strongholds of a variety of successive movements of a more or less radical character. This is true especially of rural areas where one-crop commercial farming in combination with other factors (for example, irregular rainfall) results in a high degree of economic insecurity among farmers or where a high degree of underemployment exists among agricultural workers. The depletion of forests and other secondary sources of farmers' income or their appropriation by outsiders also tends to create areas of social unrest (for example, northern Sweden and the cut-over areas in the Great Lakes states and the Deep South of the United States). In some of these areas social movements tend to find support among all social strata because all are affected; in other instances the property owners will lean toward one, the propertyless classes toward another, "extreme"

movement. Persistent centers of unrest and rebellion also occur in certain sections of metropolitan cities. The study of these phenomena constitutes the "ecology" of social movements.

### The functions of social movements

The great changes in the social order of the world which have occurred during the past two centuries are very largely the direct or indirect result of social movements. For even if a movement did not achieve all its goals, parts of its program were accepted and incorporated into the ever-changing social order. This has been the main, or "manifest," function of these movements.

As a movement grows, certain secondary, or "latent," functions may be observed: (1) the movement contributes to the formation of public opinion by providing for the discussion of social and political problems and through the eventual incorporation of some of the movement's ideas into dominant public opinion; and (2) it provides training of leaders who become part of the political elite and may eventually rise to the positions of leading statesmen. The socialist labor movements and the national independence movements have produced a large proportion of the present-day heads of government throughout the world. Labor leaders and leaders of other movements, even if they do not hold public office, also belong to the political elite in many countries, a fact which in some instances is recognized by heads of government, who may extend appropriate honors to such leaders or consult with them on political issues.

When these two functions have reached the point where the movement, after having changed or modified the social order, becomes part of it, the life cycle of the movement comes to an end—it has become an institution. This is true in the first place when a revolutionary movement is victorious, as in the Soviet Union and mainland China, where communism can no longer be called a movement but has been transformed into a regime. It is true also of the socialist labor movement and some farmers' movements in the economically advanced countries of northern and western Europe and in the United States and the British Dominions, while the countries where urgent social and economic reforms have been delayed or prevented are the present-day seedbeds of revolutionary socialistic and communistic movements.

## THE STUDY OF SOCIAL MOVEMENTS

The analysis of social movements has constituted an amorphous and diffuse field of sociological research and theory that is sometimes conceived as part of the general field of collective behavior and sometimes as part of the study of voluntary associations. In this article, however, social movements are defined as *socially shared demands for change in some aspect of the social order*. This definition emphasizes the part played by social movements in the development of social change—an aspect that no student of them has been able to ignore.

At various times and under various conditions the legitimacy of a society's customary institutions or values may come under attack from different parts of the society. New arrangements are advocated; but the demand for change meets with resistance, and old habits and arrangements are maintained. Thus it comes about that groups face each other in some form of conflict.

A social movement, therefore, is not the unnoticed accretion of many unrecognized changes. Rather, it has the character of an explicit and conscious indictment of whole or part of the social order, together with a conscious demand for change. It also has an *ideological* component—that is, a set of ideas which specify discontents, prescribe solutions, and justify change.

## Directed and undirected movements

There is a mixture of formal association and informal, diffuse behavior encompassed in the concept of a movement. A significant distinction can be made between "directed" and "undirected" movements or segments of a movement. This distinction is similar to that made by Herbert Blumer (1946) between "general" and "specific" movements. The *directed* segment of a movement is characterized by organized and structured groups with specific programs, a formal leadership structure, definitive ideology, and stated objectives. Its followers are *members* of an organization as well as partisans to a belief. The *undirected* phase of a movement is characterized by the reshaping of perspectives, norms, and values which occurs in the interaction of persons apart from a specific associational context. The followers are *partisans* but need not be members of any association which advocates the change being studied.

For example, the directed segment of the feminist movement consisted of associations that sought to achieve goals of equal rights for women in various areas of American life; in its undirected

phase, the movement consisted of a subtle and unreported redefinition of the rights of women (in which both men and women played a part). In Ibsen's *A Doll's House*, Nora was a partisan participant in such a movement, without any affiliation to a feminist organization.

These two sides to the phenomenon of social movements often lead to diverse emphases among sociological studies. Those which focus on diffuse and undirected action are likely to emphasize those characteristics of movements which are akin to other phenomena of collective behavior and which are often such a striking feature of the early formation of movements and associations. Crowd and mob action, generalized unrest, and the structure of personal commitment loom large in many studies of the genesis of social movements (for example, see Cantril 1941). This type of study attempts to analyze the ways in which discontent is made specific in new definitions of rights and privileges, indictments of the existing order, and, finally, in programs for new institutional structures. For example, in George Rudé's (1959) analysis of public opinion among working-class Parisians on the eve of the French Revolution, the origin of their discontent is traced to anger at rising bread prices; only through a series of riots, statements, and counteraction did the protests of the workers become defined in an ideology of revolution.

Most studies of social movements have been researches into the career of an association, from stages of collective excitement to the activities of formally organized groups. In such studies the movement is identified with the goals and actions of organizations (see, for instance, Holtzman 1964; Lipset 1950; Webb & Webb 1894).

## Public policy and private persuasion

Directed and undirected segments of social movements affect each other. As movements arise, grow, and become recognized, they tend to generate public controversy. Uncommitted portions of the society may be polarized into partisan support on the one hand and resistant opposition on the other. The Negro civil rights movement in the United States during the 1960s transformed a relatively quiescent white population into resisters and supporters of civil rights. Even where organizational membership is lacking, people take positions and adjust their behavior in response to new expectations. Issues emerge where consensus had existed (Hyman & Sheatsley 1964).

Social movements may be distinguished according to whether they seek to achieve their goals

through *public policy* or *private persuasion*. A movement may work toward the goal of effective change in the rules of government or other institutions. For example, the Townsend movement sought to gain legislation affecting the welfare of the aged (Holtzman 1964), and the early Methodist sects hoped to reform the Anglican church (Niebuhr 1929). Other movements have concentrated on persuading individuals to a line of action and have ignored the use of public institutions as agents of control. Religious movements are more likely to seek converts than new legislation. Even in the American temperance movement the early stages were marked by efforts to persuade individuals to abstain (Gusfield 1963, chapter 2).

**Belief and politicization.** Although movements may, and often do, utilize both public policy and personal persuasion, it is important to recognize that they may shift their emphasis from one to the other. The ways in which movements become politicized is thus one of the important problems in the field. The religious expression of discontent may substitute for political expression (Lipset 1960, pp. 97-100). The contrary trend is also found; for instance, studies of millennial movements in Melanesia show that religious movements are capable of turning into nationalistic political rebellions (Worsley 1957).

The concept of a "social movement" is thus suggestive of people who, on the one hand, are in process of rejecting existing social values and arrangements, while, on the other, they are both striving to make converts to their way of seeing things and dealing with the resistance that their activities inevitably call forth. But while the movement is often carried by associations, it is not wholly an associational phenomenon. It is in the *system of generalized beliefs*, and in partisan commitment to such beliefs, that we find the characterizing features of a social movement. The unity and coherence of a movement, in its various stages and forms, depend on the similarity of the adherents' beliefs about the legitimacy of a new way of behaving, of their rejection of what has been, and of their demand for adoption of the new. This is what distinguishes a social movement from other types of special interest associations and from those hostile outbreaks and expressive protests which do not develop into explicit demands for a changed society.

### Social change and the social base

A major hypothesis in the field is that social movements are the products of social change. Circumstances arise in which long established relationships are no longer appropriate; the result of

this strain between old and new is discontent. One of the sociologist's tasks in analyzing a movement is to identify the particular social changes that have generated discontent and to specify their relation to the movement. For example, a movement toward establishing the language of Norwegian rural areas as the official Norwegian language was shown to be a product of the cultural chauvinism with which peasants responded to the influx of urban institutions and personnel in the provinces (Munch 1954).

**Social bases of movements.** Just as change is seldom uniform throughout a society, so too a social movement usually appeals to some segments of a society but not to all. In other words, it has a location in the social structure. For example, the Indian independence movement had a special attraction for Indian professionals who were, as a class, blocked from full professional attainments, although they had been given a British education (Misra 1961); the Poujadist movement in France attracted small businessmen and farmers (Lipset 1960, pp. 154-165); Methodism in its early stages had a singular appeal to the British working class (Niebuhr 1929, chapter 2).

A specific movement, of course, may appeal to more than one social or cultural segment. Analyses of movements often involve consideration of the problems posed by efforts to unite diverse social groups in one association. Thus, it has been shown that the American socialist movement was constantly troubled by the diversities arising from a rural, native American radicalism and the radicalism of urban, often immigrant, workers. Native American radicalism was both Populist and anti-industrial, whereas urban, working-class radicalism has sought to extend industrialization, provided that it is regulated (Bell 1952).

**Relative deprivation and social change.** There is no simple unilinear relation between the hardships experienced by a group and the development of movements toward change. The principle of *relative deprivation*, however, goes some way toward explaining the relation between perceived deprivation (or threat of deprivation) and the expression and organization of discontent. Research has shown that the absolute situation of a group is not as instrumental in generating and focusing discontent as is the *perception* of what is just, expected, and possible. Revolutions may, and often have, occurred just after revolutionary segments of the population have improved their economic position. Because of a group's rising expectations, the new situation may be experienced as even more distressing than the previous one. In some cases, fear of the loss of new gains may instill and in-

crease unrest. Furthermore, the loss of past status may be influential in generating movements which aim at restoration. This was one factor in the development of British trade unionism; early industrialization threatened to erase the line between craft and unskilled labor and thus threatened the position of the skilled worker (Webb & Webb 1894, chapter 1).

**Structural aspects.** Potential supporters of social movements must also be assessed from the standpoint of their skills and opportunities for the development of collective action. Social change may generate movements through structural changes, such as an increase in the capacities of groups for the tasks of communication, leadership, and organization. For example, colonial education acts as a training ground as well as a seedbed of discontent for anticolonial nationalist movements (McCully 1940).

**Ideological content.** The beliefs of any social movement reflect the unique situation of the social segments that make up its base. Taken together, these beliefs amount to a *paradigm of experience* by which the ideology and program of the movement appear right, just, and proper only to a particular segment of society, because it alone has undergone the experiences which could make the ideology seem both relevant and valid. This is true even though the ideology may be set forth in quite general terms. For instance, the movement for an amendment to the United States constitution prohibiting discrimination on the basis of sex has been stated in the rhetoric of equal rights for all women. This amendment has been sponsored, however, by upper-class women who would benefit from equality with husbands in property rights and has been opposed by working-class women who achieve special protection and welfare benefits under laws which limit their hours of work (Green & Melnick 1950). In this case, the rhetoric of "equal rights" has a different meaning for working women than for upper-class women.

### Career of social movements

In analyzing the relation of social movements to social changes, the sociologist, as we have seen, characteristically attempts to identify the social segments uniquely supportive and "open" to the movement, the social changes that produce both the discontent of these segments and their means for expressing it, and the relation between the ideological content of the movement and the specific social situations of the adherents and the partisans.

**Collective behavior to collective action.** However, discontent alone is far from being a sufficient cause of either protest activity or of more explicit

demands for change. "A movement has to be constructed and has to carve out a career in what is practically always an opposed, resistant, or at least indifferent world" (Blumer 1957, p. 147). The generalized unrest must become focused on specific parts of the social order. New beliefs must be created and adherents gained. People must be activated to champion a cause through the mobilization of their energies in a concerted manner. As this occurs, the movement often takes on new characteristics.

Whether or not an initial discontent will become organized into a movement is itself problematic. Hobsbawm (1959) has studied a number of what he calls "archaic" movements, in which diffuse protest did not coalesce into organized demands for change. Thus, Sicilian social banditry of the nineteenth and twentieth centuries, both expressed and was nourished by the diffuse protest of the Sicilian peasantry against the rich and the "outsider." However, such protest never achieved an ideological content or an organization through which to focus on a program of demands, tactics, and strategy.

The appearance of agitation in the midst of unrest aids in the development of new perspectives toward the social order and gives meaning to the social changes producing discontent. The development of leadership, organized actions, and ideology mobilizes discontent into an organized movement and frequently generates new characteristics owing to an initial outburst of energy. Thus, initial outbreaks of violence may well go beyond the attack on a specific and defined part of the *status quo*. In the Hungarian revolt of 1956, the urban riots were not revolutionary in origin, but they took on a revolutionary character as the movement favoring a new regime took on a more organized and permanent structure (Gross 1958, pp. 319-321). Without the appearance of a more permanent structure, such outbreaks are likely to be isolated events, as were the Harlem riots of 1943.

**Contingencies.** Events which are unanticipated and beyond the control or influence of the movement often change the constellation of resisting and supporting forces and thus strongly affect its career. For example, the inflation of the 1920s and early 1930s contributed heavily to the development of the Nazi party by increasing the economic discontent of lower-middle-class groups whose emotional ties to nationalism had already made them likely adherents of National Socialism (Fromm 1941; Lipset 1960, pp. 138-152).

**Structural conduciveness.** The structure of society affects the origin and form of movements in a variety of ways. This phenomenon has been re-

ferred to by Smelser (1962) as "structural conduciveness." Dissent may be condoned in one society but so prohibited in another that the movement must take the form of a secret society. For instance, according to the theory of Selig Perlman (1928), the unique features of the American labor movement were a product of the openness of the American class structure. In Europe, Perlman argued, workers could not find solutions to their economic discontent by moving out of the working class; by contrast, in the United States the workers' prospects for upward mobility were fairly good. It followed from this that American workers were less class-oriented and political in their union aims than European workers and more oriented to immediate issues of wages and conditions of work.

### The study of social movements

The literature of sociological theory contains a plethora of typologies of movements. Such typologies are often developed in terms of concern for the development of a theory of movements. However, few research studies of specific social movements have been concerned with the development of a theoretical framework; most studies have been motivated by the researcher's interest in particular social issues and philosophies. The field of social movements can be profitably described in terms of the historical, political, and ideological concerns which have been the focus of research since the mid-1920s.

**The problem of commitment.** The rise of communist parties in most Western nations as well as the development of German fascism has deeply affected students of political and social movements. Even the study of medieval and other millenarian religious movements has been actuated, in recent years, by a parallel interest in the mass political movements of the twentieth century (see MILLENARISM; see also Cohn 1957).

Sociological and social psychological studies of extremist movements have attempted to identify the sources of the organizational and ideological loyalty of adherents and partisans. "Fanaticism, enthusiasm, fervent hope, hatred and intolerance" often mark the advocate of revolutionary change (Hoffer 1951, p. xi). The fierceness with which the communists, fascists, and other "extremists" of left or right adhere to their positions of power is contrasted with the conditions of democratic politics. Rudolf Heberle (1951, chapter 15) has even drawn an analogy between totalitarian parties and religious disciplines by referring to the former as "political orders."

**Interpersonal relationships.** A major hypothesis in the study of the commitment process is that

loyalty to a movement is fostered through the network of interpersonal relationships built up in the process of participation. The initiate to a movement develops personal ties which support and enforce doctrinal commitments. The socially alienated person finds in a movement a solution to his problems of "belonging." Studies of defection among British, French, and American communists reveal that their behavior was influenced by dual and conflicting interpersonal loyalties, such as that of family or work team on the one hand and the party on the other (Almond 1954; Crossman 1949). In some movements, totalistic commitment is fostered by a round of life so controlled by organizational activities as to preclude interpersonal relations outside of the movement; where this happens, defection is tantamount to a complete reorientation of one's life. In more pluralistic movements, adherence to the movement does not cut the member loose from other competing and even conflicting roles.

**Psychological studies.** The discussion of the roots of "extremist" adherence to communism and fascism has also been approached from the standpoint of psychology. The research of T. W. Adorno and his associates (1950) into "authoritarian personality" has led to a widely held view that a constellation of masochistic and sadistic personality traits predispose some persons toward antidemocratic, intolerant, and authority-centered political positions and movements. In criticizing this thesis, Edward Shils (1954) has shown that right-wing, xenophobic, and nativist organizations in the United States have demonstrated a great inability to subordinate to united leadership and that diverse personality types are needed within the same organizational structure if a movement is to be effective. Similar psychological syndromes of intolerance for ambiguity among the partisans of both the extreme right and the extreme left in England and the United States have been discussed by Milton Rokeach (1960). Toch (1965) has developed a useful framework for analyzing the psychological motivations and consequences involved in membership commitment for a wide range of diverse movements.

### Bureaucratization of social movements

The development of at least a semipermanent organizational structure is often essential to the realization of the goals of a movement. However, such organization often sets in motion influences which defeat the ideals that gave birth to it. This is the paradox: that which is a needed means to an end is often the means which frustrates attainment of the end.

Disillusionment with the possibility of achieving ideals through organized movements has provided the motivation for many studies of social movements in the twentieth century. A major source of concern for this "blurring of mission" has stemmed from religious ideology: How can the ideals enunciated in religious thought and prophetic criticism be translated into effective institutional structures? Ernst Troeltsch (1912) was the first to pose this problem with some degree of theoretical precision when he made a distinction between *sect* and *church*. He maintained that as a sect develops into a more regularized and coordinated church organization (with a definitive membership, a trained clergy, and specified dogma and ritual), the initial mission and emotional drive of sectarianism is diffused in the accommodative perspective and rational character of the church. There is some confirmation of this hypothesis in various studies of American and British religious movements; new sects develop among the "disinherited" poor who find that the established churches no longer meet their needs. Such "churches of the disinherited" in turn display tendencies to become more conservative or "churchlike" (Niebuhr 1929; Pope 1942; Harrison 1959).

**Routinization and commitment.** Contemporary sociologists have often pointed out how the idealism and missionary zeal of spontaneous emotional commitment to a cause tends to be "corrupted" by the tendency of all organizations to become "ends-in-themselves." Max Weber's doctrine (1922) of the *routinization of charisma* is the leading theoretical statement of this view.

A number of studies of political and other movements have been inspired by similar concerns. Robert Michels' study (1911) of the German Social Democratic party in the early twentieth century has been the most influential work in this vein; his doctrine of the *iron law of oligarchy* emphasized the inevitability of a conservatizing leadership in organized movements. Several recent studies have also shown the tendency of movements to remain in existence beyond the realization of their original aims (Messinger 1955; Sills 1957). Implicit in this type of study is a "natural history" theory of organizations: they simply grow old like any natural organism. But more recent research suggests that the problem of institutionalization is far more complex. There would appear to be no inherent tendency either in organizations or in the sources of organizational commitment to move toward accommodation and compromise and thus to weaken the ardor of membership and the definiteness of the program. Not all unions lose their factional characteristics (Lipset et al. 1956);

not all sects become churchlike as they become regularized and stable (Wilson 1961); not all organized movements become accommodative (Gusfield 1955). The fate of a movement is dependent upon many factors, among which are the contingencies which affect resistance, as well as those which change the character of the initial adherents.

### Mass movements and mass society

The fact that highly industrialized societies seem to be especially likely to produce mass movements of various kinds has led scholars to inquire if there is not something in the very nature of mass society that encourages this tendency. Indeed, the conception of modern society as "mass society" has been one of the leading themes in the study of contemporary social movements. Exponents of this point of view hold that in contemporary industrial society traditional groups and institutions have lost control over the loyalties and behavior of the individual. The weakening of primary group attachments and the impersonal character of large-scale organization alienate men from the sources through which a democratic political process is mediated to citizens and achieves its legitimacy. Such alienated people are easily mobilized around charismatic leaders and symbolic goals. Thus, Hannah Arendt's study (1951) of European totalitarian movements traces their development to the destruction of a class structure in which group affiliation had governed behavior and attitude.

From the standpoint of this type of theory, we would expect leaders and adherents of contemporary antidemocratic movements to be drawn from segments of the population that are not well integrated into social units. William Kornhauser (1959, chapters 9-12) has shown this to be the case for a wide range of European and American totalitarian movements: not only are marginal members of society less "open" to control by elites, organizations, and primary groups, but they are also most apt to be attracted by the camaraderie of association and by the antiestablishment ideology so often found in radical movements of the right or left.

Other writers have introduced views and findings critical of mass-society theory. They maintain that organized and integrated groups are essential to effective movements and that new perspectives toward the social order are developed in the supportive context of primary and secondary group organization. According to this view, contemporary society has not shattered group structure, nor are the conditions of modern industrial society as "alienative" as the theorists of mass society have maintained. Socially alienated people, it is argued,

lack the essential social organization within which shared meanings could emerge in the first place; contemporary social movements can be expected to arise, as have other movements, among discrete social bases. For instance, S. M. Lipset has shown that the preponderance of support for German fascism, French Poujadism, and American McCarthyism has come from the lower middle classes in response to the threats of industrial development; similarly, the preponderance of communist support in Europe has come from the working classes and not from marginal, socially alienated persons (Lipset 1960, chapter 5).

### The wake of colonialism

Since the rise of various new nations in areas that were formerly European colonies, sociologists have recognized a need for the study of anticolonial nationalism and of the impact of social change on political and social movements in nonindustrialized societies. The study of nativism and revivalism under colonial domination has shown a tendency for such movements to be the precursors of movements for national independence. In general, analysis of nationalist movements has shown their relation to changes in traditional society which are caused by colonial policy (Van der Kroef 1955).

The revolt of Negroes against white domination constitutes a special chapter in the history of social movements since World War II. While racial tensions have been part of nationalist movements in many African and Asian countries, such movements have been most striking in South Africa and the United States, where their goal has been greater equality rather than national separation. However, the general movement of developing nations toward independence has had an impact even in the United States, as indicated by the appearance of a Negro nationalist movement (Essien-Udom 1962).

## SOCIAL PROBLEMS

Social problems are described most simply as perplexing questions about human societies proposed for solution. The distinctiveness of such questions as a separate object of sociological study rests upon their topicality, currency, and pragmatic

derivation. Social problems are part of the climate of opinion in society which centers on expressed needs for public policies and anticipated requirements for social control. Social problems study or research consists of the ordering of perspectives and social facts in relation to the ends and means of collective action.

Proceeding beyond this general statement to a more precise definition of social problems poses a complicated task of sorting out the wide diversity of views held by sociologists as to the nature of the subject matter and the perspectives from which it should be studied (Merrill 1948). These conflicting viewpoints, as well as salient misgivings shared by many as to whether social problems is a "field," or can validly be included with sociology, are in part understandable in the context of the origins and history of sociology itself.

### History of social problems approach

Concern with social problems has been singularly American or Anglo-Saxon. Antecedents can be found in the literature of socioeconomic criticism and reform which was directed at many of the consequences of commerce, industrialism, and urban growth in western Europe, particularly eighteenth-century and nineteenth-century England. The more immediate forerunners of what came to be the social problems approach emerged from writings, reports, essays, and surveys by Protestant clergymen, philanthropists, and middle-class humanitarians, in the United States as well as England, who were dedicated to a variety of social reform activities. These included prison reform, settlement work, child rescue, promotion of temperance, housing betterment, and improvement of conditions of employment of women and children; by the middle of the nineteenth century many of these had crystallized into organized actions or associations.

The roots of the intellectual orientation toward social problems as an academic subject are more precisely located in the broadly based American reform movement from which, in 1865, there issued the American Social Science Association. This represented a merger of a variety of local and regional associations, whose constituted objectives were clearly meliorative (Bernard & Bernard 1943). In large part it was responsible for the introduction of social science courses in American colleges and universities, beginning in 1865 and reaching a peak between 1885 and 1895. Many, if not most, of these courses, however titled, dealt with topics subsequently recognized as the substance of social problems courses in sociology—

with possibly somewhat greater attention paid to education and law.

The development of such courses reflected motivations of persons both within and outside the universities who were seeking to arouse and prepare students for careers of legislative reform. The courses attained quick popularity with students, many of whom were repelled by limitations of the classical or science curricula and who were fired by the social ferments of the post-Civil War period. Toward the end of the nineteenth century, when sociology began to receive formal departmental recognition in colleges and universities, many of those recruited to teach it came from backgrounds of the ministry and welfare work. The lineal ties of their versions of sociology to the older social science movement are attested by the substantial numbers of these early sociologists who were members of the National Conference of Charities and Corrections and of the American Prison Congress (Sutherland 1945).

**The scientific rationale.** Such facts strongly tempt one to the conclusion that American sociology was fathered by the study of social problems. However, this is opposed by another theme, reflecting continuity with the thought of August Comte and Herbert Spencer, holding to a scientific purpose in the study of society, which was present almost from the first in the social science movement. To the scientific emphasis in pioneer American sociology was added an antireform bias, stemming from the laissez-faire philosophy of Spencer and sounded in W. G. Sumner's strident disdain for social welfare activities. The conflict of purposes among early sociologists is epitomized by the lengths to which Sumner himself went in devising titles which would sharply distinguish his courses from the reformistic ones taught by his colleagues at Yale Divinity School.

It is generally accepted that Lester F. Ward's teleological philosophy outweighed the influences of Spencer and Sumner in the formative years of American sociology and that the notion of an "applied sociology" became or remained dominant. Yet the applied sociology of Ward (1906) was little more than an idea which took its concrete meaning from classroom teaching, student field trips to charitable institutions, and the writing of textbooks, a number of which appeared in the first decade of the twentieth century. These, as well as the ones which followed, drew heavily on factual data from a variety of sciences construed to have a bearing on the problems under discussion, roughly ordered into "causes," "effects," and "solutions." This was consistent with Spencer's concep-

tion of sociology as a synthetic, "capstone" science, but this scientific rationale probably made a virtue of necessity. The amount of "pure" sociology available for application to social problems was severely limited; early sociologists, like Yankee inventors, made do with materials at hand.

**Changing perspectives.** The passing of time saw the social problems approach in sociology lose ground as the socioeconomic characteristics of recruits to the field changed and as the need to validate sociology's status as a macrocosmic science was increasingly accepted. In the middle decades of the twentieth century sociologists turned more and more to self-conscious discussion of methodology, research design, and theory, with a growing attention to the European sociology of Max Weber and Émile Durkheim. A kind of ideological commitment to social neutrality and nonevaluative research took hold of the discipline. The gulf between social theory and the study of concrete social problems grew wide, intellectually stranding many sociologists with continuing interest in the latter (Davis 1957). Their discontent culminated in the establishment in 1952 of the Society for the Study of Social Problems, which, while affiliated with the American Sociological Association, nevertheless carefully cherishes its separate identity.

Despite the shift in perspective regarding the fundamental tasks in sociology, the flow of textbooks on social problems has continued unabated, and courses so titled continue to be taught—albeit more restively by a younger generation of sociologists trained to demand theoretical meaning in materials with which they deal. The attenuated identification of sociologists with social problems courses is perpetuated by the relatively large number of students attracted to their offerings who nevertheless do not plan to follow sociology as a course of study. Instruction in social problems courses in otherwise scientifically oriented sociology departments is given various rationales—general education, a "service function," or a means of recruitment of students to the field.

Other pressures also have made it difficult for sociologists to disengage themselves from the old ties to social problems. Government recognition of military uses of sociology during World War II, plus research support from industry, government, and private foundations after the war, drew the interest of sociologists toward applied research on problems posed by persons or agencies outside the field. The massive surge of the American Negro after 1954 toward greater equality of opportunity multiplied the contingents of sociologists at work on applied research. The looming threat of thermo-

nuclear war motivates others toward immediately useful, rather than abeyant, "scientistic" sociology. A number of highly articulate critics both within and outside sociology have inveighed against the sterility or inapplicability of much contemporary theory, directly challenging the claim that sociology can or should aspire to ethical neutrality.

### Theoretical issues

The most sweeping indictment of social problems writings appeared in an article by C. Wright Mills (1943) entitled "The Professional Ideology of Social Pathologists." With slashing phrases he more or less condemned an entire generation of social pathologists for the low conceptual level of their textbooks, the discrete and unrelated nature of their treatments of various social problems, and insertions of rural-biased value judgments in the guise of objective terminology. These observations, while undeniably cogent and pointed, were closer to stricture than to science, although they were organized around Mills's own brief for structural analysis of social problems data.

Closer study and more sanguine assessment of the field in the past make it less atheoretical than it would seem, especially if the textbooks are disregarded in favor of provocative articles by Frank (1925), Waller (1936), and Fuller (1937; 1938; compare Fuller & Myers 1941a). These writers, especially Fuller, both saw and sought to analyze social problems in a general setting of values and value conflict. Fuller's distinction between ameliorative problems and moral problems, implications of which he developed in a paper on morals and the criminal law (1942), bears insightfully on structural questions concerning the relationship of values to norms and the contingency of legal action on variations in this relationship.

Both Frank and Fuller stressed a holistic view frequently repeated by many contemporary sociologists, i.e., that situations or behavior considered to be problems, on finer analysis prove to be expressions of cherished values or institutionalized norms crucial to the operation of society. From this came Fuller's conclusion—dismal to some—that solutions to social problems may be or are impossible. This, when fitted with his later effort to demonstrate a natural history of social problems (Fuller & Myers 1941b; Lemert 1951a), closely allies his thinking with the *laissez-faire* philosophy of Sumner, but it is also akin to the political conservatism many sociologists believe to inhere in modern "system" theories of society. In sum, these critics seem to say that putting social problems into a structural context destroys both

ideological rationale and the individual motivation for reform, by showing the problems to be "necessary" consequences of a given type of value system or by making clear that values will have to be sacrificed and institutions disrupted if the problems are to be eliminated.

**Definition as an issue.** The first authors of books on social problems bothered little or not at all about definitions of social problems, uncritically drawing on fairly homogeneous convictions about the aspects of society that needed improvement or reform. Among the first attempts at definition were those of Ellwood (1915), Howerth (1913), Kelsey (1915), and Hart (1923). The prevailing definition, however, came from Case (1924), who was attracted to ideas of Thomas (1909) dealing with generic elements in the process of cultural origins. Predominant among these was an element of *attention*, defined as the subjective or reciprocal aspect of social control, which is activated by crises (Thomas [1917–1937] 1951, p. 218). These ideas led Case to propose that social problems are situations impressing a large number of competent observers as needing remedy by collective action. They became for him and many others after him sociopsychological phenomena; social problems, stated most simply, are whatever a goodly number of members of society say they are.

This definition more or less identifies sociologists with the lay populace and makes public opinion sociological opinion, with implied faith in a democratic process. Its difficulties accrue from recognition of the irrational or spurious qualities in public expressions or collective behavior, which counsels considerable discounting of public reactions or moral indignation as guides for sociological criticism of society or its institutions. Moreover, questions must be faced as to how many or what persons qualify as an acceptable panel for making judgments as to what are social problems. Many issues in modern society are articulated almost exclusively within coterie of specialists in health, medicine, welfare, correction, and education. They reflect technical interests, often couched in esoteric language, which are projected into the arena of public opinion only ephemerally or adventitiously.

Superficially, Fuller's distinction between moral and ameliorative problems seems to reconcile the older conception of social problems with the facts of technical specialization. However, the division between moral and technical problems often becomes vague or disappears, for means may become ends or ends means, depending upon the vantage point of the beholder. The older idea that social

problems could be defined by a consensus of professional and welfare experts made little headway with sociologists, largely because judgments of specialists outside their own or adjacent areas of interest can claim no greater validity than those of educated lay persons. Representative specialists often are spokesmen for organized groups, necessarily supporting vested agency values as well as conveying judgments derived from technical knowledge. Finally, it must be noted that the ordering of social problems with respect to priority or importance cannot be determined by consulting specialists who define them distributively.

### Social pathology

The subjectivism inherent in the "popular" definition of social problems runs athwart the conception of sociology as a body of knowledge which rises above common sense and is accumulated through application of special methods by observers or researchers at least relatively detached from the social facts under scrutiny. If social problems are defined in terms of such a body of knowledge, they become objective rather than subjective facts, "discoverable" from laws or generalizations about necessary conditions of social life. Despite its well-documented shortcomings, the bare idea of social pathology is more congenial to such a formulation of sociology than is that of social problems.

Social pathology was an effort to apply a biological or medical model to the analysis of problematical phenomena of society. It rests on the idea that societies or their constituent parts may develop abnormally or anomalously and that they can be described or "diagnosed" in the light of some pristine or universal criterion of normality or health. The orientation of social pathology was, however, toward man rather than society, being heavily pervaded with the nineteenth-century concern about the relevance of institutions to the perfectibility of human nature. The notion of individual adjustment figured large in discussions of social pathology, revolving about the consequences of physical illness, mental deficiency, mental disorders, alcoholism, lack of education, or incomplete socialization for the realization of life goals regarded as normal for most people. The fact that many of these conditions are indeed associated with organic pathologies or were assumed to have a hereditary foundation lent strength to the idea that social problems were external, or objective, facts. Sociological residues of this idea persist today among those who believe alcoholism and mental disorder to be diseases. In the perspective of time it may be said that so long as American society was domi-

nated by middle-class values, laissez-faire individualism, localism, and southern regionalism, the more absolutistic conception of social problems as social pathology remained tenable.

### Social problems and social disorganization

The growth of cultural relativity in sociology, infiltrating from the critical-historical themes of American anthropology, together with the general questioning of paramount American values that was generated by the great depression of the 1930s and by foreign revolutions, put an end to social pathology as a viable perspective on social problems. The need for concepts to organize thought about societies in wholesale flux and crisis was conjoined with the need to place discussion of social problems in a more comprehensive intellectual scheme that would be in keeping with the methodological aspirations of sociologists. The needs in part seemed met by restatement of conceptions of social disorganization originally set down by Thomas and Znaniecki (1918-1920) and Charles H. Cooley (1918). Many of the phenomena that had long been the subject matter of social problems or social pathology now were postulated as symptoms or products of such processes as uneven cultural development, conflict, dissensus, and dialectical change. Taken together, these processes mean social disorganization. A pivotal distinction was set up between social disorganization and personal disorganization, with the latter assumed to be functionally associated with the former. On this point most textbook writers followed the organic analogy of Cooley rather than the ideas of Thomas and Znaniecki, who saw no necessary relationship between the two.

While some sociologists have decried texts on social disorganization as being little different from those on social problems, apart from their introductory chapters, this ignores the lively development of ecological studies by sociologists at the University of Chicago and elsewhere, whose findings appeared to give statistical support for the notion that social problems are expressions of a common, underlying social process. For a while, at least, the idea of "disorganized areas" in urban communities became established sociology and a welcome new way of ordering the data in textbooks. Vice, crime, poverty, divorce, and mental disorder all became part of a zonal or area parcel explainable in terms of generic ecological growth, change, and deterioration.

Social disorganization as a subject has the look of an impressive theoretical façade which on closer analysis is disillusioning. The concept of process

on which it relies is vague at best, and the distinction between social and personal disorganization is difficult to maintain. Serious doubt has been cast on the method of ecological correlation, undermining the neat idea of disorganized areas. Careful ethnographic studies of the slum, such as W. F. Whyte's *Street Corner Society* (1943), make it undeniably clear that such areas can be or are relatively well organized. [See *DEVIANT BEHAVIOR*.]

The idea of social disorganization still has its theoretical partisans and, defined simply as human activities or failures to act which impede or block other activities, is indeed demonstrable and of heuristic value. Thus, if artillerymen fire shells that, by reason of faulty communication or function, fall on their own troops, the result is fittingly enough described as social disorganization. But if questions are asked whether the attack was part of integral tactics, or whether the associated campaign advanced over-all strategy, or whether the war should have been fought in the first place, theoretical analysis quickly moves into speculation where fact and value blur. In any but a specifiable, closed social system or subsystem with consensual goals, the formulation of social disorganization reduces to value choices of its author.

### Social problems as dysfunctions

Forms of thought from the traditions of European sociology and English anthropology offer the theoretical alternative of subsuming the data of social problems under the category of social dysfunctions. This descriptive and analytic device proceeds from assumptions that there are functional prerequisites of social life around which institutional structures operate, mutually supporting each other, meeting psychobiological needs of individuals, and contributing to an over-all integration of society. Practices or activities which run counter to functional prerequisites, which disrupt the institutional nexus, or frustrate individual needs are defined as social dysfunctions.

The difficulties of functional analysis are well known. Determining what is indispensable to maintain a specific complex of behavior and what is adventitious is made difficult by the fact that the range of cases or time series in human societies from which to generalize often is small and some kinds of events have only a few instances. Culture comes to each generation in unsorted bales or packets, and historical, comparative, or cross-cultural studies are limited in their potential for sorting out that which is functional or dysfunctional. When cultures change or undergo disruption, that which may have seemed to participants or ob-

servers to be a causal or functional association may turn out to be dispensable. The social problems of yesteryear often live only as the quaint reminiscences of today.

The persistence of ancient social problems or dysfunctional activities in such forms as crime, political corruption, gambling, or prostitution in the face of collective efforts to eradicate them is not readily explained by functional analysis. An explanation for such seeming paradoxes was proposed by Robert K. Merton (1949, chapter 1) in the form of a distinction between "manifest" and "latent" functions; R. M. Williams (1951) also dealt with this matter in his discussion of "patterned evasions of institutional norms." However, these explanations seem secondary or residual at best. They call attention to the fact that actions may have functions as well as dysfunctions. In another light, they are implicit concessions that determination of functions in a culturally diverse society depends in large degree on the particular needs, perspectives, or values adopted by the observer.

A more crucial but closely related issue in functional analysis is whether it can reveal those activities which can be established in objective terms as social problems, even though they are not necessarily subjects of popular awareness or collective action. In a general way Case (1924) heeded this question when, in defining social problems primarily as aspects of the collective mind, he nevertheless recognized that statisticians and others could describe *adverse conditions* of society; furthermore, the inclusion of a "situation" in definitions by a number of other sociologists was recognition that objective factors were a necessary part of social problems (Smith et al. 1955). Ogburn (1922), more clearly of functionalist persuasion and impressed by the discrepancies between dynamic technology and institutional adaptation, sought a totally objective definition of social problems as consequences or expressions of "cultural lag." Subsequent critics showed that this conception was not, as hoped, free from value judgments and strongly argued against its underlying dichotomy of material and nonmaterial culture.

The causal relationships between technology, culture, and moral ideas and the sequence in which they change continue to be among the great moot questions of sociology. They have grown more prominent as ruling groups in some societies seek to assist others to industrialize or raise agricultural productivity. The discovery in many instances that introduced technology does not always lead to the expected consequences has compelled students of

socioeconomic development to conclude that their judgment of what is functional and dysfunctional for others is not easily imposed for the purpose of directing change.

### Social problems as deviation

Since 1940 a sizable portion of the traditional subject matter of social problems, such as crime, delinquency, prostitution, drug addiction, and physical handicaps, has been categorized as deviance, deviation, or deviant behavior. The amoral, statistical, or descriptive implications of the terms carry a strong appeal, although they tend to acquire morally invidious connotations. Generally, deviance is defined as violations of norms, or departures from social expectancies, but beyond this minimal agreement the ideas projected for its analysis differ considerably.

One group of sociologists, following Durkheim, Parsons, and Merton, has concentrated on sources of deviation in discontinuities, anomie, or strain within the structure of a society that is assumed to be more or less an integrated system. The analysis of deviation in this theoretical context is voluntaristic, in contrast with deterministic or strictly causal versions of functionalism. Deviation originates from permutations of choice by individuals motivated by culturally given ends and confronted with means of varying accessibility. The most cogent statement or theoretical design derived from these ideas appeared in Merton's widely influential article "Social Structure and Anomie" (1938).

Critical assessment of the structural or "anomie" interpretations of deviation was slow to crystallize but was finally made by a symposium of sociologists qualified by extensive research in areas of deviation. In this volume, edited by Marshall B. Clinard (1964), they raised serious doubts as to whether Merton's effort to design an embracing theory of deviation was sufficient for the complexities of the data. The ends-means distinction is not an easy one to maintain with concrete data, and the individual motivational base of structural sociology is barren ground for the production of a theory of group-related deviation in any but reactional terms. The heavy accent on conditions of social order in works of Parsons (1951) reduces social control to a negative mechanism for repressing deviation; the recognition of deviation as a creative necessity for social change is absent from structural theories or appears only in revised afterthoughts.

Standing at considerable theoretical distance from the objectivism of current structural theories of deviation are the productions of a small nucleus

of sociologists represented by Erving Goffman (1963; 1961), Howard S. Becker (1963), and Edwin Lemert (1948; 1951b), whose perspectives are more microcosmic than macroscosmic. Characterized by the importance they assign to interactionally derived meanings in the genesis of deviation, they have dwelt upon factors present in interaction, such as labeling, stigma, self-presentation, identity conflict, and identity protection; they have also dwelt upon the more structural concepts of role, deviant career, societal reaction, and secondary deviation. These writers do not talk of social problems, but their interests in the self-definitional and constrictive impacts of social control align them with the notion that social problems are products of definition. They are little concerned with criteria for rational social control or solutions for problems of deviation, preferring to show how agencies of reform, rehabilitation, or "treatment" give form and meaning to deviation and stabilize it as secondary deviation by intervening interaction processes.

While these sociologists offer strong negative criticism of institutional controls and public policy relevant to deviance, thus far they have not produced explanations of how definitions of deviation and related policy appear as cultural phenomena, or of how and why they change. Neither have they done much theoretically to connect deviation with innovation and creativity in the processes of change. Broadly assessed, however, interactional studies of deviation show more sensitivity than systematic sociological theory to many salient features of modern society, among which must be numbered functionally derived morality, shifting ends-means relationships, pluralistic group action, segmentalized social relationships, information control, attenuated role commitment, and the operational consequences of these for norms and rules defining deviation.

### Future of social problems approach

In some respects social problems is one of the most important branches of sociology, for it provides the testing ground for predictions and the ultimate usefulness of sociology. Yet it remains a theoretically embarrassing area for many sociologists who regard its crucial questions of definition as unanswered. Discussions and research in social problems, particularly those subsumed as deviancy, now can lay claim to a closer alliance with general sociological theory than was true in the past. However, the dilemma between subjective and objective viewpoints persists, reviving with nearly every attempt to formally delimit the field.

There are growing indications that this dilemma

may be resolvable with theory and studies of values and valuation, concepts toward which sociologists and other social scientists have been pushed by the dissensus, group conflict, and resistance which seem to be the ubiquitous concomitants of swift change in modern society. Some sociologists, and more anthropologists, have sought to discover the basis of action in a general structural matrix of values delineated by age, sex, occupation, kinship, and other status attributes; others have looked for significant values in derivative, "second order" categories, such as "personality structure." However, these researches bypass the question of how values are aggregated for a pattern of action in any increasingly pluralistic society containing tangles of competing groups and associations.

One consequence of the heightened interest in values and valuation may be the evolution of a science of social action from the more amorphous area of social problems, implemented by studies of conflict resolution and short-term change and emphasizing content as well as forms of group interaction. This requires a different imagery of social problems, one less pointed to crisis and reform and more amenable to the facts of continuous change and policy revision in high-energy societies. The notion of a solution to social problems as a synoptical "best possible" choice from a number of alternatives will prove less useful than knowledge of how decisions are made and executed the "hard way." These decisions, it is to be hoped, will be seen less as "causes" of change in static situations than as strategies for intervention into ongoing processes. If value aggregation through group interaction is an important phase of such processes, it will be no less important to specify who has access to what means of social control and to locate the relevant values of power elites; for these, too, are among the "conditions" of change.

Successful linkage of "subjective" value phenomena with "objective" social structure and technology may come from theoretical extensions of human ecology, widely conceived to show how time, space, energy, and resistance to change intrude into the sociopsychological aspects of action. This necessitates acceptance of the idea that technology can change the order of choice among values, otherwise set by culture and social structure, by altering the costs of their fulfillment. This is not to say that human beings always perceive and respond economically to "costly" ways of acting. Both the definition of social problems and the organization of rational intervention are problematical phenomena to be explained. Insofar as social scientists assume responsibility for supplying

critical knowledge for rational intervention, they help to organize it. Consequently, it is doubtful that social problems can be studied from an ethically neutral position.

## SOCIAL PSYCHOLOGY

The article under this heading provides an overview of the field of social psychology. More detailed systematic and theoretical analyses may be found in FIELD THEORY; GESTALT THEORY; MARXISM; SOCIOLOGY; THINKING, article on COGNITIVE ORGANIZATION AND PROCESSES. Concepts of general and historical importance in social psychology are discussed in ATTITUDES; COMMUNICATION; COMMUNICATION, MASS; GROUPS; IDENTITY, PSYCHOSOCIAL; IMITATION; INTERACTION; LANGUAGE; MOTIVATION, article on HUMAN MOTIVATION; PERCEPTION, articles on PERSON PERCEPTION and SOCIAL PERCEPTION; PERSONALITY; PERSUASION; POLITICAL BEHAVIOR; PSYCHIATRY, article on SOCIAL PSYCHIATRY; PUBLIC OPINION; REFERENCE GROUPS; RELIGION, article on PSYCHOLOGICAL ASPECTS; ROLE; SELF CONCEPT; SOCIALIZATION; SUGGESTION; SYMPATHY AND EMPATHY. Other relevant material may be found in AGGRESSION; ALIENATION; COALITIONS; COHESION, SOCIAL; COLLECTIVE BEHAVIOR; COMPETITION; CONFORMITY; CONSENSUS; DECISION THEORY; MASS PHENOMENA; ORGANIZATIONS; PREJUDICE; STATUS, SOCIAL; STEREOTYPES. Methods and techniques used in social psychological research are treated in ACHIEVEMENT MOTIVATION; EXPERIMENTAL DESIGN, article on QUASI-EXPERIMENTAL DESIGN; INTERVIEWING, article on SOCIAL RESEARCH; OBSERVATION, article on SOCIAL OBSERVATION AND SOCIAL CASE STUDIES; PERSONALITY MEASUREMENT; PROJECTIVE METHODS; SOCIOMETRY; SURVEY ANALYSIS. For the historical background of modern social psychology, see the biographies of ALLPORT; COOLEY; DURKHEIM; HOVLAND; LE BON; LEWIN; MEAD; ROSS; SIMMEL; TARDE.

Although its intellectual origins extend back into antiquity, social psychology as a scientific discipline has only recently come of age. Our purpose in this brief survey will be to provide a rough sketch of the current status of the field by outlining the problems, approaches, and methods of contemporary research. Specific content areas are treated in more detail in other articles.

The set of problems on which social psychology has been focused, problems that have intrigued thinkers since ancient times, concerns the social nature of man and the manner in which this social nature develops. The awesomeness of whatever

## SOCIAL PROCESSES

See ACCULTURATION; ASSIMILATION; COHESION, SOCIAL; CONFLICT; COOPERATION; INTEGRATION, article on SOCIAL INTEGRATION; INTERACTION; SOCIALIZATION.

processes are involved in the development of man as a social animal are put into bold relief by such accounts as the *Wild Boy of Aveyron* by Itard (1801). This and similar accounts of so-called feral children suggest that without human contact the infant human organism will never develop his full biological and psychological capacities. Clearly, important events occur in the early, primitive contact that the infant human has with his parents. The nature of these events, the socialization process, has become one of the central focuses of social psychology. If we conceive of socialization in its broadest sense as a process whereby the individual learns the beliefs and values of his social group and learns to adjust his behavior so that it meets the expectations of others in the group, then social psychology can be regarded as the study of socialization and its products. [See SOCIALIZATION.]

Some historical background. There are several traditions that represent different approaches to the study of social behavior, which we can touch on only briefly. The sociological tradition developed by such men as Tarde, Le Bon, Ross, Cooley, and Mead has been concerned primarily with processes mediated by face-to-face interaction. In one way or another this tradition has relied upon one or more of the triumvirate of concepts: suggestion, imitation, and sympathy [see SUGGESTION; IMITATION; SYMPATHY AND EMPATHY; and the biographies of COOLEY; LE BON; MEAD; ROSS; TARDE]. Another important contributor from the sociological side was Simmel, who attempted to distill the forms of social relationships (e.g., superordination and subordination) from the widely different settings in which they appear [see SIMMEL]. A figure who stands alone in importance in the early development of social psychology is the French sociologist Durkheim [see DURKHEIM]. He conceived of the interaction situation as generating emergent norms, or "collective representations," as he called them [see NORMS]. These norms, in turn, act with "exteriority and constraint" in controlling subsequent behavior. This intellectual tradition in sociology has melded into the approach of many contemporary social psychologists.

On the psychological side there have been three major influences: psychoanalysis, behaviorism, and gestalt theory. The psychoanalytic approach conceives of the socialization process as curbing and redirecting the infant's natural appetites, thereby producing an adult with a complex unconscious life, as well as with a conscience that operates to constrain subsequent behavior. Identification, which occurs both in the very early months of life and

in the resolution of the Oedipus conflict, represents, in psychoanalytic theory, one of the principal mechanisms of socialization. The behaviorist approach attributes social learning to the establishment of stimulus-response connections that are mediated primarily by drive reduction; social behavior is seen as a set of ingrained habitual responses and response patterns. The gestalt school, with its emphasis on the organization of the perceptual world of the individual, has focused its study on the meaning of a percept, as well as on the cognitive, conscious thought processes that are involved in interaction. The modern representatives of this school of social psychology, such as Festinger (1957) and Heider (1958), have stressed the tendency for a person to come to see his world and his own behavior and beliefs in a consistent way. [See GESTALT THEORY; IDENTITY, PSYCHOSOCIAL; PSYCHOANALYSIS; THINKING, article on COGNITIVE ORGANIZATION AND PROCESSES.]

In the past these approaches produced a great deal of sectionalism, but much blending is visible today. Workers in the field have come to realize that the various approaches need not be mutually exclusive. Social psychology is coming to be viewed as a general approach to the study of human behavior that rests, on the one hand, on certain basic facts of perception, cognition, motivation, and learning and, on the other hand, on certain basic facts that have to do with the social context which sets boundary conditions for the behavior in the form of the expectations of others. Accordingly, social psychology is in a position to borrow both from traditional psychology and from traditional sociology.

### The general approach and methodology

Any approach to behavior can be cast in the S-O-R paradigm. A stimulus (S) impinges on the organism (O) and produces behavior, a response (R). The ways in which various approaches differ is in how the S, the O, and the R are characterized. Contemporary social psychology differs from traditional psychology in this characterization. Within traditional behaviorism, for example, the characterization of the stimulus and the response have tended to be made in physicalistic terms. For example, in studies of learning, a stimulus is described as a buzzer with a particular frequency or a light with a particular wave length and the response elicited might be a bar-press or the raising of a paw. In general, social psychologists have implicitly assumed at least a two-stage process mediating responses to stimuli. The first is a per-

ceptual stage in which meaning is attributed to some external stimulus configuration and a second stage in which the meaningful stimulus generates subsequent behavior. The emphasis is on the meaning to the person of both the stimulus situation and the response.

Social psychologists have worked in two distinct settings, the everyday world and the laboratory, and have developed a research armamentarium appropriate to both of these settings. By the everyday world we mean the study of social behavior *in vivo*, in some existing social milieu. Social psychologists have studied behavior in factory settings, in military organizations, in housing communities, in delinquent gangs, and so on. Of course, it is impossible to study every aspect of the behavior of the individuals who are enmeshed in such complex situations as these. The social psychologist, therefore, narrows his sights to include only a limited number of aspects of any given everyday-life situation. He may focus on behavior in response to certain aspects of the total stimulus situation, such as the power structure of the group or the communication network that connects the individual member to others in the group. The researcher-observer is typically not in a position to control or alter features of these complex situations and is therefore limited in what he is able to infer with confidence from his observations. If a certain kind of behavior seems to be associated with a particular aspect of the total situation pinpointed by the researcher, it is impossible for him to know, without adequate control over the total situation, whether the behavior was indeed produced by this aspect of the situation or by some other aspect which the researcher failed to take into account. Furthermore, it may be that the behavior itself subsequently served in some way to generate the stimulus conditions; causal direction is difficult to infer. It may also be the case that some unknown set of stimulus conditions is generating *both* the observed set of stimulus conditions and the observed behavior—that is, the observed relationship between the stimulus and the response may be spurious. These are some of the methodological shortcomings to which research in field situations is heir. [See EXPERIMENTAL DESIGN.]

Much of the field research in social psychology has been devoted to the study of such specific problems as the way in which supervisory practices affect morale in a particular organization or how certain propaganda appeals affect the vulnerability of a particular audience. Field methods are eminently suited to finding answers to specific, press-

ing problems of this kind. The laboratory serves—or should serve—a different purpose. Because of his ability to manipulate, control, and purify the stimulus conditions confronting the person who is serving as a subject in the experiment, the experimenter acquires the ability to study behavior in more general terms. His ability to infer causal connections between the stimulus conditions that he creates and the behavior of his experimental subjects helps in developing theories regarding the underlying psychological processes—the nature of the *O*. He attempts to do this both by establishing specific stimulus conditions confronting his experimental subject and by limiting the response alternatives available to the subject. His inferences are generally made by comparing the effects on behavior of variations in the stimulus conditions with the same set of response alternatives available to the subject.

The fact that the laboratory is often used to create a minuscule social world has led some people to assume mistakenly that the main purpose—in fact, the sole purpose—of the laboratory is to try things out on a small scale before applying them to a larger, real-world context or to understand the large complex situation by re-creating a smaller situation that has the same order of complexity as the larger one, a rather ambitious program to say the least. The laboratory research worker who is investigating basic social psychological processes is not concerned with making empirical generalizations relating a specific set of stimulus conditions to a specific response, but rather with establishing conceptual laws about behavior. The mistaken testing-ground view of the laboratory is a source of much confusion. For example, it leads to the expectation that the laboratory worker should provide people in policy-making positions with immediately useful insights and specific empirical predictions concerning some specific aspect of their particular world. The field setting and the laboratory are geared to answering quite different questions. The field setting is much richer in content, but this richness also makes for tenuous inferences.

The technology used in any field study or laboratory experiment will be dictated by the specific problem at hand. Typically, a field study involves a combination of careful observation of behavior with some form of verbal report, questionnaire, or interview responses. Whereas social psychologists who engage in field studies devote a great deal of effort to refining these response measures, the laboratory worker devotes the greater part of his efforts

to refining the stimulus conditions. This difference in emphasis is due to the distinct differences between the two settings. In the field study, the investigator studies responses to existing stimulus conditions over which he has no control, whereas in the laboratory he sets out to create the stimulus conditions and usually permits only a narrow latitude of possible responses. As we review some of the research we shall see examples of individual items of technology. [See *INTERVIEWING, article on SOCIAL RESEARCH*; *OBSERVATION, article on SOCIAL OBSERVATION AND SOCIAL CASE STUDIES*.]

**The action sequence.** A general approach to behavior that incorporates aspects of a number of other approaches is that of the action sequence. Any action engaged in by the person is designed to come to terms with his changing stimulus environment so that his outcomes (satisfactions) will be maximized. He will want to transact with objects having positive value for him and will avoid objects having negative value. As compared with lower organisms, the stimulus vista of the human being is extremely broad, consisting of a wide variety of potentially satisfying and potentially punishing objects and events. Much of this complex set of value-object relationships, or attitudes, is acquired through the socialization process.

Any given act involves a decision, however simple and quickly it is made, between alternatives, each having consequences for the person. His decision—even if it is between acting or maintaining the status quo—will be predicated upon how the person sizes up the outcome potential of each alternative. A postdecisional accommodation process occurs after he commits himself to one of the action alternatives. Behavioral economy and the exigencies involved in dealing with the world around him require that the person make relatively quick decisions and then follow through. He learns to live with his decisions, since undoing them is often costly, if not impossible. Also, a decision implies giving up the positive outcomes associated with the nonchosen alternative and suffering the negative outcomes, if any, associated with the chosen alternative. A decision is forced upon the person, since he is unable to simultaneously enjoy the values associated with the various alternatives that are open to him. Vacillation is not an efficient solution. Postdecisional accommodation has been studied extensively by Festinger (1957) and others. The person's predecision stance toward information about the alternatives is an open or vigilant one, whereas his postdecisional stance is selective and defensive. This basic antinomy between vigilance and defensiveness is a fundamental characteristic

of behavior. We shall review the general field of social psychology within this action-sequence framework which considers both the predecisional and postdecisional phases of the act.

### Perceptual processes

Social psychologists have tackled the age-old and difficult problem of perception. The problem stated simply is: How is the welter of stimulus information that impinges on the person at every moment organized by him and made meaningful? The act of perception is a decision to classify some stimulus event in some particular category. This response will be determined by the total behavior context in which the perceptual act occurs. A configuration conveying stimulus information of a round red object with a stem sticking out of a small depression on the surface may in one context be perceived primarily as something to eat and in another context as something to throw. The person's "definition" of the situation will be determined, in part, by prior social learning. This situational definition consists of a set of expectations as to what stimulus objects are likely to be present within the general behavioral context and the values that the person holds as he contemplates transaction with the stimulus. A percept is a decision and as such can be analyzed within the action-sequence framework. In Bruner's terms (1957) a percept is a "solution" to a problem, the constituent parts of which are the cues provided by the object and the expectations and desires provided by the person. A good solution is defined pragmatically as one in which subsequent transaction with the object confirms the original expectation and, hence, provides satisfaction for the original desire. The perceptual process serves not only to facilitate transaction with positively-valued objects but also to prepare the person to avoid negatively-valued ones. He is continually alert to changes in his stimulus environment that may signal positively-valued or negatively-valued consequences for him.

Most of the research has been in the form of demonstrating the interaction between the stimulus and the person's values in one or another behavior context. There has been little work, however, on the exact nature of the interaction that would help to define the limiting conditions under which the interaction will take place and those conditions under which the interaction will be maximum. The findings that support this view of the perceptual process are reviewed in detail elsewhere [see *PERCEPTION, articles on PERSON PERCEPTION and SOCIAL PERCEPTION*].

A particular relationship deserves special mention here since it highlights the functional, decisional nature of perception. Under conditions of impoverished stimulation, the subject's visual threshold for positively-valued stimuli is lower than it is for neutral stimuli—that is, less stimulus information is required by the subject to recognize positively-valued objects. The findings for threatening, negatively-valued stimuli show a somewhat different pattern. Negatively-valued stimuli that can be avoided show a lower threshold than neutral stimuli, whereas negatively-valued stimuli that cannot be avoided show a raised threshold. Both of these tendencies can be interpreted as attempts at avoidance. Where the subject can take action, he is vigilant toward the threatening event, whereas where he can do nothing to avoid it he is ostrichlike in this tendency to deny its existence. [See ATTENTION; PERCEPTION, article on PERCEPTUAL DEPRIVATION.]

**Person perception.** The study of person perception is, of course, of special interest to social psychologists. The way in which one person's acts are interpreted by another will determine the course of their future interaction—that is, whether or not mutual dependence and mutual influence develop. The general findings in this area are consistent with our functionalist view of perception. The total stimulus-and-value context appears to induce expectations as to the qualities or traits possessed by the stimulus person as well as to induce attributed intentions. The fact that a person is known to possess a particular characteristic induces the expectation that he will possess other characteristics that are usually related to the one that he is known to possess. The inference made about the stimulus person from any given act is made in terms of the context of the act. Was the act justified in the eyes of the perceiver—that is, was the act appropriate to the stimulus situation attributed by the perceiver to the stimulus person? For example, if the stimulus person behaved aggressively within a context that appeared to the perceiver as one in which aggression is a perfectly appropriate response, the stimulus person might not be perceived as aggressive. He would tend to be perceived as aggressive only if another, nonaggressive response seemed more appropriate to the stimulus context. On the other hand, if the context is one in which an aggressive response seems particularly appropriate and the person responded in a nonaggressive way, the perceiver might attribute meekness to the stimulus person. The general principle operating here is that the intention attributed to the stimulus person will be inferred from the stimulus person's

behavior judged in terms of the behavioral alternatives open to the stimulus person (as seen by the perceiver). Various aspects of the total situation will determine the judgment by the perceiver as to the response alternatives open to the stimulus person—for example, the status of the stimulus person vis-à-vis the person toward whom he is acting, the sequence of interactions immediately preceding the segment of behavior in question, and idiosyncratic qualities of the perceiver himself.

**Interaction.** Man's social nature is presumably molded through interaction. Since interaction is between persons as each is perceived by the other, knowledge of the process of person perception is an important and basic key. We form an impression of a person from his interaction with us or with others and our impressions in turn condition our interaction with him. The research on social influence and other group processes, which we shall review below, starts either by assuming that the actors have certain impressions of each other or by experimentally inducing the impression, *de novo*, as an independent variable. The student of person perception examines the process in reverse by treating interaction as the independent, experimental variable and examining aspects of the interaction situation that produce various impressions. Both of these approaches complement each other, and knowledge gained from each will add to our understanding of the nature and substance of social life.

### Social comparison processes

Other persons can act as sources of information or as direct mediators of reward. The child's parents provide him with food, warmth, and shelter and also with certain knowledge he requires to engage in the business of living within his social milieu. All problems in social psychology reduce to studying implications of either one or the other kind of dependence for information and for directly mediated effects (outcomes, rewards, satisfaction).

A given act involves a beginning state, a desired end state, and a path or sequence of behaviors designed to move the individual from start to finish. Any act, however trivial, can be analyzed within this framework. Kurt Lewin referred to the possible action sequences existing for the person at any given moment as the person's "life space." There may be a considerable amount of uncertainty attached to various aspects of an action sequence. The person may be uncertain as to whether his present level of satisfaction is reasonable or whether the end state of the sequence will indeed furnish him with a higher level of satisfaction. He

also may be uncertain as to whether or not he has the ability to act in the manner required to realize the end state or to transact with the end state in order to derive the satisfaction he anticipates. To the extent that the situation is novel, his uncertainty will be high. The person's world is in constant and irregular motion, usually taking unpredicted turns. In trying to reconcile these changes with his own desires, he is continually confronted with decisions and tries to choose the action alternative that he hopes will yield him the most pleasure or the least pain. To the extent that he is uncertain about what to do or how to do it he will be oriented toward getting information to reduce his uncertainty.

The person may be uncertain about his present outcome level—that is, whether or not he is receiving adequate satisfaction in his present situation. What kind of measuring stick does he use to determine how satisfied he is? There appear to be three bases upon which he may “measure” his satisfaction: his own past experience, the various alternative outcome states potentially available to him, and the experiences of other people in the same or similar situations. It is this last basis that is of particular interest to us here. Where comparison persons are available as points of reference against which he can compare aspects of his own situation, he will make use of this information to the extent that more reliable information is lacking.

**Reference persons.** There are three basic kinds of information other persons can provide: advice, impressions, and knowledge as to relative standing. Advice is any information given to another through “instruction.” Impressions are given about the person by another through a process we shall call “reflected appraisal.” Standing refers to the person's relative position in a group, with regard to some attribute, and the process whereby he determines his standing we shall call “comparative appraisal.” Most of the research on social influence has been concerned with the last-mentioned process, comparative appraisal.

Two general types of reference persons can be distinguished: the “expert” and the “co-oriented peer.” An expert is someone who, by virtue of his experience, has special knowledge as to how the person might effect a favorable change in outcome level. A co-oriented peer is someone who shares the life situation of the person, someone who has a similar outlook and value orientation. In measuring his present or future satisfaction level the person tends to refer to others like himself. Merton and Kitt (1950) demonstrate this rather well with data on the degree to which certain groups of en-

listed men felt deprived during World War II. They found, for example, that married soldiers felt more deprived as a result of being in the army than did single soldiers. This, they discovered, was attributable to the fact that married soldiers, in measuring their outcome level, compared themselves with other married men, whereas single soldiers compared themselves with other single men. Since all able-bodied single men were in the army, the single soldier did not feel deprived relative to his co-oriented peer group. Married soldiers, on the other hand, knew that a large proportion of their peer group had evaded the draft and were enjoying the comforts of home life. They therefore felt deprived. The co-oriented peer helps the person to measure his present or potentially available outcome states, whereas the expert is a source of information on how to move from one state to another. [See REFERENCE GROUPS.]

**Social influence.** The research on social influence has been conducted in three very different laboratory settings, and our review will examine each of these in turn, within the general framework outlined above. The first setting is one in which the subject finds himself in a face-to-face confrontation with other people with whom there is some sort of a discrepancy. The second setting is one in which the subject is merely informed that he is in disagreement with others and has little or no opportunity to communicate with them. The third setting is one in which a single communicator attempts to persuade an audience.

### Communication and consensus in groups

The work of Allport (1920) brought the study of group effects on individual judgments into the laboratory. Allport's work was preceded by a tradition dating back to the turn of the century, in which group effects on individual performance were demonstrated. Allport found that a person's judgment about an ambiguous stimulus can be influenced by the judgments of other people about that stimulus. In subsequent work, Sherif (1935) found that this modified judgment, the norm, tends to persist even in the absence of these other people. We can see the close connection here with Durkheim's concept of collective representation. [See GROUPS, article on GROUP FORMATION.]

The advent of World War II spurred the development of social psychology, especially in the area of social-influence processes. The next important milestone was provided by the work of Kurt Lewin and his students. Lewin realized very early the importance of systematic theory in studying behavior, and he also had an abiding faith that even

complex social behavior could be studied systematically in the laboratory. Of particular concern to us here are his studies of group decisions. These studies, which were undertaken during World War II, suggested that when an individual reaches a decision in a group situation, the decision appears to have a compelling quality in sustaining certain consequences of that decision (Lewin 1947). Some doubt has been cast on the conclusions reached in these early experiments, by some more recent work of Bennett (1955). In her attempt to replicate with more careful controls the earlier group-decision experiments, Bennett found that it was the decision itself that carried the day rather than the fact of having reached a decision in a group. Bennett discovered, however, that the individual's attitude toward the decision was positive to the extent that there was consensus in his group. This, then, may have been the crucial mediating factor in Lewin's experiments—namely, that where a group decision was made, the individual group member was made aware of the group consensus. [See CONFORMITY; CONSENSUS; GROUPS.]

**Attraction of the group.** Lewin's "discovery" of the power of the group inspired the work of a number of his students. One set of studies that was so inspired was undertaken by a group working with Lewin that was led by Festinger. The first of these was a field study by Festinger, Schachter, and Back (1950) of social pressures in a student housing community in the Boston area. Within the community, "natural" groups were created by the architectural design of the community; families were thrown together because of the way in which the individual apartments were arranged. The central finding of the study grew out of the fortuitous occurrence of an important, controversial issue that arose while the study was in progress. The investigators found that the degree of unanimity of opinion on the issue within each of the architecturally circumscribed groups was a direct function of the over-all attraction of the individual members to these groups. There is a strong suggestion here that the more attractive a group is for an individual member, the greater will be the tendency for the member to be influenced by the opinions of others in the group. This interpretation led to more general speculation about the nature of social influence processes and eventuated in a program of laboratory research that occupied Festinger and his students for a number of years. Typically, the experiments used college-student subjects engaged in a discussion during which their behavior was carefully observed and meas-

ured. Three types of behavior were recorded: an attempt by the subject to influence someone else in the group, an attempt by the subject to reject someone in the group, and a change of opinion by the subject on the issue that was being discussed. The amount of each of these three kinds of behavior, it was reasoned, would indicate the strength of the tendency for the group to reach a consensus. With these behaviors as the dependent variables, various aspects of the group situation were manipulated experimentally. The suspected relationship found in the housing study mentioned above—namely, that the greater the attraction of a group for its individual members, the greater will be the tendency for members of the group to reach a consensus—was verified (e.g., Schachter 1951; Festinger et al. 1952). It was also found (e.g., Schachter 1951) that the greater the relevance of the issue to the purpose of the group, the greater will be the attempts to reach consensus. To the extent that the members of the group are able to refer their opinions outside the group for validation, there will be a weakened tendency to achieve consensus in the group (Festinger & Thibaut 1951). Studies by Festinger and Thibaut (1951) and Gerard (1953) found that the greater the discrepancy in opinion between members of a group, the greater will be the tendency for them to influence each other. To the extent that a given group member is close to the modal opinion in the group, he will attempt to influence those who are deviates to change their opinion, so as to achieve greater group consensus (Festinger et al. 1952; Gerard 1953). Reaching consensus in a group involves getting deviates to change their opinions. When such attempts fail, consensus can be achieved by rejecting these deviates. Any basis that may exist for conceiving of the deviate as not being a relevant reference person will tend to enhance rejection as a method for achieving consensus (Festinger & Thibaut 1951; Gerard 1953). There is also evidence that the individual will be more vulnerable to influence from someone who is an expert than from someone whose ability is equal to or less than his own (Festinger et al. 1952).

All of these experiments growing out of the housing study were designed to study information dependence that is engendered when the individual is uncertain about some belief or opinion that he holds. Other people, it was assumed, are used merely as reference points against which the person may check his opinion. The process based on this kind of referral, comparative appraisal, can occur with or without actual face-to-face confron-

tation. When, however, people do confront each other face-to-face, reflected appraisal may also take place. Here the person is responding to what the other person may think of him for being a deviate; he will respond not in order to reduce uncertainty, but in order to maintain or improve his status in the other person's eyes. In these experiments the subjects were confronting each other face-to-face, and it is likely that their responses were in part due to reflected appraisal. It is not clear, for example, why attraction to others in the group should increase the person's tendency to refer his opinions to that group, unless we assume that reflected appraisal is operating—that is, that individual members are concerned with maintaining their status in the group. Where the person is concerned with reducing the uncertainty with which he holds a belief, referral should be based upon how much expertise the person attributes to the reference person and not to how attractive he is. There is another possibility that may account for the relationship between comparison and attraction. Insofar as the aspect or judgment being compared with others in the group has anything to do with present or future satisfactions—that is, outcome perspective—there will be a greater tendency to rely upon the judgments of others to the extent that they are perceived as co-oriented in this respect. It may be that where a person is highly attracted to others in the group, he assumes that they are co-oriented peers. Another possibility that was addressed experimentally by Berkowitz (1957) is that an individual will attribute expertise to someone he likes. In any event the original problem with which these studies began—namely, the relationship between the tendency to reach a consensus in a group and attraction by the members to the group must be mediated by either attributed co-orientation or attributed expertise. A great deal of work remains to be done in order to understand the nature of the mediational processes involved. [See COHESION, SOCIAL.]

**Further studies of social comparison.** An important field study conducted by Newcomb (1943) in the middle and late 1930s at Bennington College, a women's college, offers striking evidence regarding the attainment of consensus in an existing group. Newcomb traced the changes in attitudes toward political affairs that occurred among Bennington students during their four years of college. The typical Bennington freshman in 1935, the year the study began, came from a wealthy northeastern conservative home and reflected this background in her attitudes upon entering Bennington. Most of the faculty were left of center

in their political attitudes. As the situation developed, it was "in" to be a liberal, and most of the upperclassmen expressed liberal attitudes. The longer the student remained at Bennington, the more liberal her attitudes became. That this was not a mere overt public avowal, but a reflection of her actual attitudes, is attested to by a follow-up study of the attitudes held by these Bennington students thirty years later (Newcomb 1963), in which it was found that there was very little reversion to the conservative attitudes held by these women when they were entering Bennington freshmen nearly three decades earlier.

A series of experiments initiated by Schachter (1959) studied comparative appraisal as mediated by attributed co-orientation. Whereas the earlier experiments were concerned primarily with the comparison of beliefs, Schachter's experiments were concerned with comparison of emotions. Emotions are strong attitudes and, as such, have a belief and a value component (see the discussion below on attitudes). The value component has associated with it a substrate of physiological arousal. Since the value component is paramount in the case of an emotion, a person who is uncertain about some aspect of an emotional experience he is having will seek out co-oriented peers—that is, others undergoing or about to undergo the same emotional experience. Schachter found evidence for this in an experiment in which he threatened subjects with a strong electric shock. In subsequent experiments additional evidence was found that emotional uncertainty does lead to information dependence on co-oriented peers.

There is also evidence to indicate that the performances of other people are sometimes used by the person to estimate the quality of his own performance. A study by Chapman and Volkmann (1939) demonstrated a "group effect" on the person's aspiration. Where the subject had no clear expectation as to what his performance would be on an unfamiliar task, he utilized information about the scores others had made on the task, in setting his own level of aspiration. On the other hand, where the subject had had considerable experience with a particular type of task and could therefore estimate fairly accurately how he would perform on a similar task, knowledge of the scores others had made had little or no effect on his performance aspiration.

Other studies have shown that when a task is a competitive one, the person will seek his own level in choosing a competitor. This finding is taken by Festinger (1954) as evidence for a tendency on the part of the person to compare his

performance to the performance of others as a way of evaluating his ability.

### The conformity conflict

The research on consensus attainment in groups was, for the most part, concerned with events taking place in the group as a whole and did not pay specific attention to the individual member's reactions to a discrepancy confrontation. And elegantly simple experimental situation designed by Asch (1956) provides a technique for bringing the individual's reaction into sharper focus. This is accomplished by confronting the subject with unanimous disagreement from a group of peers (who are actually accomplices of the experimenter) on a very simple, unambiguous visual judgment. The judgment involves matching the length of a single line to one of a number of comparison lines. The subject confronts repeated disagreement from "the others" on a series of trials. Asch found that there was a tendency for some subjects to yield to the group judgment.

In a situation like this the subject assumes that the others possess approximately the same perceptual capacities as he does and are able and willing to report accurately what they see. How, then, can there be a discrepancy like this? These considerations make up the informational side of the conflict. There is also the problem of standing out like a sore thumb, the subject's concern with the kind of impression he is making on the others if he assumes that they expect him to agree with them. If he disagrees with them he may lose status in their eyes. We can anticipate, then, that both comparative and reflected appraisal will be operating in the situation. An attempt to separate these two processes was made by Deutsch and Gerard (1955), by comparing a treatment in which the subject made his judgments in full view of the experimental accomplices with a treatment in which the subject made his judgments within the privacy of an isolation booth. Less yielding was found when the subjects were isolated from each other than when they were face-to-face, suggesting that reflected appraisal is a strong component process of the face-to-face situation. A number of other experiments have substantiated these results. [See CONFORMITY; CONSENSUS.]

Information dependence on others appears to increase with increasing ambiguity of the judgmental material (e.g., Asch 1956). If we assume that an ambiguous stimulus will lead to uncertainty, this finding supports the basic assumption underlying comparative appraisal: uncertainty leads to information dependence. When there is

information dependence a clear "expert effect" has also been found—namely, that when confronting an ambiguous situation, the subject is dependent upon the others to the extent that he perceives them to be expert in the kind of judgment he made (Samelson 1957). One might be led to assume by the results of these experiments on relative ability that the person with high ability has little difficulty in remaining steadfast, that he simply discounts the discrepant information as being unreliable, and that it is the low-ability person who is in trouble. An attempt to explore the psychological impact that disagreement has on individuals of different ability was made (Gerard 1961), using physiological responses to measure the impact of disagreement. The findings in these studies indicate that the greater the person's ability, the greater will be the impact of disagreement with a group of peers. This result may be interpreted by assuming that the higher the person's ability, the greater the conflict between the two sources of information available to him, the information from his own senses and the group consensus. The greater his ability, the more credibility will he attach to his own judgments which are in disagreement with another highly credible source of information, the group consensus.

In an experiment involving relatively strong attitudes, Kelley and Woodruff (1956) found that disagreement with a group of co-oriented peers was more effective in changing the subject's attitude than disagreement with a group that was represented as not being co-oriented with the subject.

In a number of investigations, explicit effect dependence was induced by making the subjects dependent upon one another for certain outcomes (Deutsch & Gerard 1955). This effect dependence produced greater conformity to a false consensus, an outcome presumably mediated by the subject's desire for acceptance in situations where the others are potential mediators of satisfaction for him. A particularly crucial finding that is relevant here comes from a study by Kelley and Shapiro (1954), in which a negative correlation was found between conformity and the acceptance of the subject as a group member. Evidently, the less the subject's acceptance, the more anxious was he to please the other members of the group. Additional supporting evidence was found by Harvey and Consalvi (1960), in whose study the most and least accepted members of a group conformed less than a member who was only partially accepted. We can interpret these results by assuming that the person of highest status does not conform because

he is assured of his status, whereas the person of lowest status does not conform because he sees no possibility of improving his status.

Other studies have been concerned with the role of commitment in the conformity conflict. Deutsch and Gerard (1955) discovered that when the subject committed himself to his judgment before being apprised of the judgments of the others in the group, he yielded much less to the group consensus.

In terms of the action sequence, we would expect that the decision to yield to the group or remain steadfast would have postdecisional consequences. Evidence reported by Gerard (1965) suggests that postdecisional accommodation does indeed take place. A conformer will accommodate both by increasing the degree to which the group is attractive to him and by attributing expertise to them, whereas a deviate will tend to reduce the perceived attractiveness of the group and attribute lower expertise to them as a way of justifying his own behavior.

### Attitude change

We will attempt a brief but broad overview of the area of attitude change in order to show how our general framework applies to this area as well. We shall examine, in turn, characteristics of the three aspects of the persuasion situation: the communicator, his message, and his audience. This is the framework used by Aristotle in his *Rhetoric* and by Hovland, Janis, and Kelley (1953) in their classic work. [See ATTITUDES, article on ATTITUDE CHANGE.]

An attitude designates the outcome potential the person associates with some object or class of objects. He consequently has a tendency either to approach or avoid that class of objects. The structure of an attitude can be represented as a syllogism in which the minor premise is a belief, the major premise is a value, and the conclusion is the attitude itself. Thus, a prejudiced person might be characterized by the following syllogism as part of the structure underlying his attitude:

Negroes are lazy.

Laziness is bad.

Therefore, Negroes are bad.

An analysis of this syllogism shows that "Negroes" is the minor term, "laziness" is the middle term, and "bad" is the major term. Many attitudes, such as anti-Negro prejudice, have complex structures that include sets of parallel syllogisms all having the same conclusion and a "deep" vertical structure with interlocking premises—that is, working backward we may find that the premises in a first-

order syllogism may be conclusions of one or more second-order syllogisms, and so on. There has as yet been no attempt to describe systematically the structure for a given person, although case studies such as those reported in Smith, Bruner, and White (1956) represent a start in that direction.

**The communicator.** Propaganda appeals are directed toward changing either the belief or value premises underlying an attitude. The credibility attached to a message will depend upon the degree of expertise or co-orientation attributed to the communicator, expertise being more important where a belief is a target of the message and co-orientation being more important when a value is the target. Experiments (e.g., Aronson et al. 1963) have demonstrated a positive relationship between the credibility of a message and the amount of expertise attributed to the communicator. An experiment by Weiss (1957) provides indirect evidence for the relationship between credibility and co-orientation of the communicator.

An aspect of the situation that is closely related to co-orientation has to do with the intent attributed to the speaker by his audience. If he is perceived as wanting to influence them, it may be in pursuit of some value he holds that his audience perceives as inimical to their own values. Therefore, to the extent that the communicator is seen as not attempting to influence his audience, the effect of any attributed lack of co-orientation would be minimized. An experiment by Walster and Festinger (1962) compared the effectiveness of a communication when it was accidentally overheard with a situation where the communicator was aware of his audience (and his audience of him) and found that there was greater attitude change in the direction of the message when it was merely overheard. [See COMMUNICATION, MASS.]

**The communication.** An aspect of the message that has been given some attention concerns the question of whether it is more effective for the communicator to present only his side of the argument or to present the other side of the issue as well. The results of this research are inconclusive. There does seem to be some evidence, however, that when a person changes his attitude in response to a two-sided communication, this change will be more likely to sustain itself than if he changes in response to a one-sided communication. It may be that a two-sided communication presents the person with a definite decision, and the communication's ability to sustain a change may be due to postdecisional accommodation. [See PERSUASION.]

**Primacy versus recency.** When presenting both sides of an argument, is it more effective for the

communicator to present his side first or second? This question reduces to whether a "primacy" or a "recency" effect will dominate. Again, the research findings do not offer unequivocal support for the predominance of either effect. Some studies have shown a primacy effect, whereas others have shown a recency effect. When the subject commits himself to an opinion after hearing one side of the issue before hearing the other side, a strong primacy effect occurs (Hovland, Campbell, & Brock 1957). This effect can be interpreted as being caused by postdecisional accommodation to the "premature" opinion commitment. A study by Miller and Campbell (1959) suggests that some of the contradictory evidence has been due, in part, to methodological problems that arise in presenting the messages and measuring their effects. As with a number of other problems we have discussed, a great deal more research remains to be done.

*Implicit versus explicit conclusions.* Another question for which there is no satisfactory answer is whether or not the communicator should draw his conclusion explicitly at the end of his talk or whether he should let his audience participate by "putting two and two together" for themselves. Aristotle suggests that a message that allows the audience to draw its own conclusion will be more effective. In our terms, conclusion drawing is a decision which, because of postdecisional accommodation, will sustain the effect of the message—if the audience draws the intended conclusion. A study by Hovland and Mandell (1952), however, suggests that conclusion drawing by the communicator is the more effective technique. Cooper and Dinerman (1951), on the other hand, find that conclusion drawing by the communicator blunts the effectiveness of a message. It is probable that particular circumstances will determine which technique is more effective, and the job of future research is to learn what these circumstances are.

*Conditioning effects.* Staats and Staats (1958) used a classical conditioning situation to manipulate the belief premise of an attitude and then measured the degree to which the middle term transferred value to the minor term that had originally been associated only with the major term. The results show that mere contiguity with positive or negative values will impart a positive or negative value to a term that was neutral to start with. Razran (1940) conditioned subjects to respond positively or negatively to formerly neutral stimuli, with a subtle technique of associating the neutral term with faint, but perceptible, unpleasant odors or the circumstance of munching away on

an appetizing free lunch. Powerful effects such as these are probably being induced without our awareness during the course of a normal day. These effects, which appear to occur without our awareness, are paralleled by effects that are based on conscious, cognitive inference. Where beliefs are shown by the communicator to further certain values, attitude change can be produced (e.g., Di Vesta & Merwin 1960).

*Boomerang effects.* There is evidence that messages that embody very strong emotional appeals may boomerang (e.g., Leventhal & Kafes 1963). The reasons for this are not very clear, although there is some suggestion in the data that strong value appeals induce defensiveness, especially where the attitude is difficult to change.

*The audience.* Obviously, the effectiveness of any message will be determined by the degree to which it is successfully tailored to its intended audience. A communication intended to induce new toothbrushing habits in an audience of eight-year-olds would not have the same impact on an adult audience. Factors such as the pre-exposure attitudes of members of the audience, the degree of familiarity with opposing points of view, their education and background, and their degree of commitment to their initial positions will all affect the degree to which they will be susceptible to a given message.

*Pre-existing attitudes and forewarning.* Hovland (1959) points out that one of the features distinguishing field studies from laboratory experiments on attitude change is the lack of forewarning of the audience that exists in the laboratory situation. In the "real world" a person selectively exposes himself to one or another propaganda missile, whereas the laboratory subject is a captive audience. Hovland suggests that this difference may be one of the factors accounting for the greater relative effectiveness of propaganda attempts studied in the laboratory, where the subject can be caught off guard, so to speak. Studies (e.g., Freedman & Sears 1965) have demonstrated that a forewarned audience is a forearmed audience and is less vulnerable to the communicator's message than an audience that has not been forewarned. An ingenious experiment by Festinger and Maccoby (1964) indicates that partially distracting the audience while the message is being presented will tend to increase the audience's vulnerability to the message.

Research by Cooper and Jahoda (1947) suggests that the prior attitude of an audience will affect how a message is interpreted. This is in line with Asch's suggestion (1948) that the context in

which a statement is heard will, in part, determine its meaning for the person. Since the effectiveness of a message hinges on its getting across to the audience, interpretation operates as an important influence in the situation. A study by Hovland, Harvey, and Sherif (1957) demonstrates that one of the factors involved in the interpretation process is the degree of extremity of the message from the subject's own attitude. Messages that are close to the subject's own position tend to be assimilated to that position, whereas messages that are inconsistent with his position are seen as even more discrepant than they actually are.

In a series of studies McGuire (1964) has shown, using an immunological analogy, that small doses of the propaganda prior to an actual full-scale attack will stimulate the person's defenses against the message. McGuire used cultural truisms such as "You should brush your teeth at least twice a day" as the opinions that were attacked. He points out that the average person's prior preparation to defend these truisms is minimal, that they have grown up in a "germ-free" environment and are therefore particularly vulnerable. Whether small doses of propaganda are able to stimulate a person's defenses regarding controversial issues remains to be seen.

*Role playing.* A procedure that has been used extensively both in training and in psychotherapy requires that a person play the role of someone else. This experience presumably gives the trainee or the patient some idea of what it is like to be the person whose role he has taken. He is able to develop an approximate version of the other person's world and in so doing comes to develop something of an understanding of what it is that is producing the other person's attitudes and behavior—that is, he becomes co-oriented with him. The first systematic attempt to investigate the effect of role playing was made by Janis and King (1954). The question they asked was, Is it the fact of verbalizing statements having to do with the other person's point of view or is it simply a matter of being exposed to that point of view that produces the change in attitude claimed for role playing? They were asking, in effect, whether role playing is really any more effective than the typical attitude change procedure that exposes the subject to an opposing viewpoint. Their data suggest that role playing does add something over and above merely being exposed to the message. The decision to play a role, like any other decision, involves all of the elements of the action sequence. The person is confronted with a choice of whether or not to play the role. If he chooses to play the role, he

must somehow come to terms with this decision. The efficacy of role playing may, therefore, hinge on the process of postdecisional accommodation. [See *ROLE*.]

We would expect attitude change to be greater to the extent that there was little other justification for playing the role. The person with little justification would be hard put to justify taking a discrepant viewpoint. One way of justifying the role-playing decision is to accommodate by finding the role itself attractive. This would tend to induce a positive attitude toward the discrepant viewpoint being advocated. Evidence that attitude change is inversely proportional to the incentive given to the person for playing the role is provided by Brehm and Cohen (1962). These experiments used monetary incentives to induce the subject to advocate an opinion that was discrepant from the subject's private opinion and found that the subject changed his private opinion more with a lower incentive. Other experiments have used inducements such as helping the experimenter in his research or the warmth and friendliness of the experimenter and found the same inverse relationship between attitude change and the amount of incentive. The principle operating here is that the greater the incentive, the less will be the necessity for the person to justify his decision. Other studies, using negative incentives—that is, coercion—have discovered that the greater the perceived freedom of choice in playing a role, the greater the amount of postdecisional attitude change. An important experiment by Mills (1958) found that when a person engages in forbidden behavior, the less the incentive for doing so, the more lenient does he become in his attitude toward the forbidden behavior. If the person decides not to engage in the forbidden behavior, the greater the original incentive for engaging in the behavior, the more severe does he become in his attitude toward the forbidden behavior. Festinger and Freedman (1964) suggest that behavior justification of this kind may be an important mechanism in the development of moral values. When a child engages in behavior prescribed for him by his parents or when he decides not to engage in behavior that is forbidden by his parents, to the extent that justification for his decision is low he may subsequently justify the behavior by coming to believe that it is the morally correct way to behave.

### Social interaction

The study of social influence shades over into the more general study of interaction. In the research discussed above, the focus has been limited

to an influence attempt by one person upon another with no influence being exerted in return. Where two individuals confront each other face-to-face, typically the behavior of one is influenced, at least in part, by the behavior of the other in a *seriatim* fashion. Each, to some extent, controls either information or effects (rewards, outcomes) for the other. It is through this control, as we have seen above, that both behavior and attitudes are shaped.

There have been several approaches to the study of the *seriatim* situation. A line of investigation started by Greenspoon (1955) has proved fruitful. The paradigm in these experiments is for the experimenter to reward the subject for saying certain kinds of words by either a nod of his head or saying "Good" or "Mmmmm." This is done in such a way that the subject is usually not aware that he is being rewarded in this way. For example, the subject might be rewarded for saying plural nouns or naming types of fruit. The subject's tendency to say these words after the experimenter no longer rewards him for doing so is shown to increase as a function of reward. Cohen, Greenbaum, and Mansson (1963) have shown that a period of prior social deprivation enhances the effect of this kind of reward. We can conclude from the considerable work carried out in this tradition that mutual control is probably governed in part by the administration of social reinforcements.

Sidowski, Wyckoff, and Tabor (1956) designed a "minimal" social situation in which to study the applicability of learning principles derived primarily from animal studies to the social contingencies that exist in mutual human interaction. The situation utilizes two interdependent subjects, each being unaware of the presence of the other. Each subject makes a choice between two possible responses. One choice rewards and the other choice punishes the other subject. Subjects soon learn, in spite of their being unaware of each other, to choose the mutually rewarding pair of responses. Further studies (e.g., Kelley et al. 1962) have explored factors that enhance or detract from the two subjects hitting on mutually rewarding responses. Informing the subject that his behavior affected the rewards of someone else and that someone else affected his rewards appears to enhance the rapidity with which the mutual contingency is "solved." These experiments seem to have abstracted the minimal elements involved in cooperative behavior, where the person can best serve himself by helping the other. Responses that reward another will tend to be reciprocated and will therefore be rewarded in turn.

Studies of a more complex nature have been carried out in which the joint payoff is arranged so that mutual trust is necessary in order for responses to be mutually rewarding. It is possible in these "games" for each player to "double-cross" the other and, if he is successful, to achieve a reward that is larger than the reward that would result from a mutually cooperative response. Thus, there is a temptation to be asocial. Also, in the process, the other player suffers at the expense of the first player getting a very large reward. A number of investigators (notably Deutsch 1958) have studied conditions under which a social, cooperative response will be made in spite of the temptation that exists to make an asocial response—that is, conditions under which mutual trust will develop. Some factors that appear to foster trust are the possibility for communication, benevolent behavior on the part of the other person, the presence of a common enemy, the absence of mutual threats, and a balance of power.

In a programmatic attempt to study techniques of augmenting one's power in an interaction situation, Jones (1964) has examined conditions under which one person in a relationship will tend to be ingratiating. Ingratiation is illicit behavior in which the person attempts to improve his status in the relationship by appealing to extrarelational values held by the other person. Any relationship is defined by the kinds of rewards each person supplies for the other. To the extent that one of the parties cannot supply the rewards expected of him, the other will tend not to reciprocate. If he is badly in need of the outcomes the other person can potentially provide, he may resort to illegal means in order to obtain them, ingratiation being one possible strategy. The person will attempt to make himself attractive to the other by being a "yes man," by flattering the other, or by attempting to emphasize additional values that he may be able to offer the other. He may resort to any one or all of these tactics. The research indicates that a low-status person will tend to resort to ingratiation to the extent that it is important that the person please the other and to the extent that he perceives that the other may be manipulated by such techniques. [See INTERACTION.]

We have confined this survey to a general overview and to a specific consideration of certain basic processes of perception and social influence. Extrapolation from these processes can be made to a number of problem areas that come within the domain of the social psychologist. The proliferation of the two-person situation generates social

structures in which each person's relationship to others in the structure is defined by behavioral expectations and rewards to be acquired by the person and by the rewards that he is expected to provide for others. He may enter into a relationship of mutuality with one or more other persons within the structure. In order for a structure to function effectively, certain norms of belief and conduct peculiar to the structure tend to develop. Situations arise in which it is necessary for one person to assume the responsibility for coordinating the behaviors and interactions of the others. These considerations have brought the study of leadership within the purview of the social psychologist. Social psychologists have also been involved in the study of large-scale organizations, in which subgroups are articulated into an over-all structure. [See ORGANIZATIONS.]

## SOCIAL ROLE

See under ROLE.

## SOCIAL SCIENCE FICTION

The creation of imaginary worlds for the purpose of exploring the potential development of society represents one of the oldest traditions in literature. The classic list begins with Plato's *Republic* and includes Bacon's *New Atlantis*, More's *Utopia*, Campanella's *City of the Sun*, Swift's *Gulliver's Travels*, and Butler's *Erewhon*. Bellamy's *Looking Backward* (1888) ushers in the modern era. Subsequent examples are Zamiatin's *We* (1925),

Huxley's *Brave New World* (1932), and Orwell's 1984 (1949), which have been described as "black utopias," or "dystopias."

A common characteristic of this literature is an emphasis on the social landscape rather than the individual protagonist, on the articulation of artificial models of society rather than interaction between fictional counterparts of people in real life, on projections from reality rather than variations of actual social situations. Articles elsewhere in this encyclopedia deal with other aspects of this genre. [See LITERATURE, article on POLITICAL FICTION; UTOPIANISM.] This article focuses on a more recent variant of the genre: the novels, novelettes, and short stories that have proliferated since World War II and which can be grouped under the rubric "social science fiction."

### Scope

The term "social science fiction" can usefully be employed to identify narratives that extrapolate from current social science concepts in order to predict or speculate about the future shape of society. This new genre of fiction stems from two literary traditions: the modern utopias and dystopias mentioned above and classic science fiction, whose early practitioners were Jules Verne and H. G. Wells and which continues to proliferate. In fact, social science fiction is a contemporary development of classic science fiction: it involves the same imaginative leaps into the future, it uses some of the same stylized conventions (time travel, interplanetary explorations), props (spaceships, robots), and characters (aliens, androids), but only as incidental backdrops to a new category of concerns. It differs from classic science fiction in two important respects. First, whereas classic science fiction is concerned with predicting the shape of the physical world through imagining the favorable and adverse potentialities of the physical sciences, the organizing concept of social science fiction is speculation about the future of society through projecting potential innovations in the knowledge and techniques of the social sciences. Second, social science fiction takes the technological innovations of the future more or less for granted and focuses on their social consequences.

Social science fiction is occasionally produced by known writers of more orthodox literature; the bulk of it, however, comes from the pens of immensely prolific writers who specialize in science fiction. The knowledge of the social sciences displayed by most of these writers is understandably naive and superficial since it is obviously gleaned secondhand from popularizations of the various disciplines.

Much of social science fiction is so inept in style and plot that it hardly merits consideration as literature, even according to the most tolerant critical standards. Much of it is published between the same lurid magazine and paperback covers as is classic science fiction and is announced in the same penny-dreadful blurbs. As a result, it has shared the same fate of being dismissed by literary critics as a minor, cultist offshoot of traditional literature, of interest only to an intellectually limited circle of *aficionados*. To the social scientist, however, the emergence of a vast body of literature on the periphery of his academic vision, which incorporates—however inaccurately—his specialized perspectives, is of more than casual interest.

### Significance

Social science fiction is noteworthy on several levels: first, as a cultural phenomenon; second, as a medium of social commentary and criticism; and third (perhaps parenthetically) as a pleasant counterpoint to some of the more pedantic complacencies of the social scientists.

As a cultural phenomenon, social science fiction provides evidence of the growing impact of the social sciences on popular culture, just as the older genre of classic science fiction documented popular interest in the successive stages of the technological revolution of the nineteenth and twentieth centuries. Between Jules Verne's 1870 submarine and the predictions of nuclear fission and space travel of the 1930s and 1940s, radical changes took place in the perspectives and expectations of the average man—changes that were in part wrought by innovations in the physical sciences. With the closing of the gap between imaginative pseudo science and almost prosaic reality, with the advent of atomic power plants, satellite traffic jams, and space walks, popular interest in the fictionalized potential of the physical sciences has become jaded. There is mounting evidence that it is being superseded by a fascination with the potential applications of the social sciences. The form this interest takes and the purposes to which writers of social science fiction bend—or distend—current knowledge in these fields constitute the subject matter of this article.

That social science fiction is an instrument for social commentary and criticism, ranging in tone from earnest concern to outrageous parody, from macabre warnings to comic alarums, is inherent in its subject matter. Three major themes are discernible both in the plethora of wildly imaginative worlds of science fiction writers and in the works of more sober and orthodox writers. The first of these centers on the social aftermath of some

cosmic disaster. These "post-doomsday" stories begin with the collapse of civilization, the agent of destruction being a nuclear war or a natural catastrophe, such as a drastic change in the weather, an epidemic, or a massive ecological imbalance. The events of the cataclysm provide dramatic interest, but they are incidental to the main theme of the story, which deals with the disintegration of social institutions, the breakdown of mechanisms for social control, and the emergence of new leaders, a new social system, and a new culture.

The second major theme consists of serious extrapolations from (or gleeful projections *ad absurdum* of) trends in contemporary society. These range from uncontrolled population growth or total depletion of crucial natural resources to such cultural aberrations as mass drug addiction or psychosis, the rampant development of fads, ultra-conformism, or the total commercialization of society.

The third major theme is the exploration of the effects upon individuals of life in unbalanced or truncated social systems. Novels in this category are concerned with what *might* be if one element in society (such as teen-agers) should seize control, or one particular technique of planning be allowed to dominate (as in the total planning for consumption), or one particular set of values (such as hedonism) becomes an enforced mode of behavior. The settings are skewed models of society built by writers with an experimental bent whose point of departure is the question "What if . . .?" and whose concern is with the processes and techniques of social manipulation.

Social science fiction is essentially moralistic. The writers of post-doomsday stories ask what happens to ethical and cultural values in the midst of social disorganization and chaos. Writers with a satirical purpose fabricate unidimensional societies top-heavy with absurd exaggerations of today's mores or aspirations for the express purpose of watching them topple. The creators of Orwellian nightmares exalt the struggle for individual freedom against the enslavement of will and intellect and sound warnings of the stultifying effects of rigid one-class or multiclass stratification systems. Like the insistent hum of the diabolical machines of classic science fiction, there is in social science fiction an undercurrent of distrust of the potentialities of unbridled social scientism—of the potential menace of techniques of indoctrination, planned acculturation, population control, and the use of statistical averages as required behavioral norms. The "mad scientist" has been replaced by a species of more plausible villain: the smooth organization

man, the amoral advertising tycoon, the cynical censor, the bland but dictatorial bureaucrat, the voracious practitioner of motivation research, the psychiatrist-in-power and his squad of ubiquitous "medicops," the amiable psychologist in charge of "preconditioning." The death ray has largely been superseded by the giant computer, and even the spying telescreen used by Big Brother in 1984 has been supplanted by the television wall, the controlled alternative to "real" social participation—"the family" as it is called in Ray Bradbury's *Fahrenheit 451* (1953). Much of this distrust of the role and the technology of the social sciences, it is well to remember, is simply the result of inadequate understanding, as well as a reflection of a fundamentally populist bias against all science.

### Types of social science fiction

With this outline of the scope and significance of social science fiction in mind it is desirable to turn to some specific examples. Some represent "purer" specimens than others in the sense that they draw upon one discipline, or one topic in a discipline (such as learning theory), for the setting and action. Others, particularly the panoramic novels, chronicle the death and rebirth of civilization. The pseudo histories of the future—such as Walter M. Miller's *A Canticle for Leibowitz* (1959), which describes a feudal theocratic society that is the preserver of civilization between atomic holocausts—borrow concepts from all the social sciences. Nevertheless, for present purposes it is possible to group the examples selected according to one or another disciplinary label. Since many of the works of social science fiction described are concerned with the subject matter of political science, that is, with the nature and locus of power and authority in society, and since several examples of political science fiction are described elsewhere, political science is not included as a separate category [see LITERATURE, article on POLITICAL FICTION].

**Anthropology.** The popularization of anthropology and its subdisciplines has provided new insights and perspectives to an entire generation of writers of fiction. In particular, the concept of culture as a holistic approach to the varieties of human life has had an impact perhaps comparable to that of psychoanalysis.

A reflection of this impact is found in those novels and short stories whose main preoccupation is with the components of culture; with the dynamics of culture change under stress; with the rise and development of new cultures on earth under primitive conditions following some trau-

matic event which destroys contemporary civilization; or with the description of different cultures in other worlds in some distant future and the attendant problems of communication and contact between cultures.

*Earth Abides* by George R. Stewart (1949) shows evidence of having been inspired by the concepts of cultural anthropology. Two themes permeate this story, which concerns a handful of survivors in a world that has been nearly depopulated by a mutated virus. First, the founder and leader of "The Tribe"—as the group is called—fails in his attempt to teach the children who are born into the group the values and customs of the old civilization. Each society must develop its own cultural symbols, Stewart seems to say, if it is to survive and grow. A miner's hammer owned by the leader, for example, becomes the focal symbol of his authority. Second, the emergence of the new culture illustrates the conflict between the individual and society. When a straggler appears on the scene and it is discovered that he has a venereal disease, the elders vote to hang him in order that The Tribe may survive. After the execution, the leader reflects on the meaning of what has been done:

This was an end, and this was also a beginning. It was the end of those twenty-one years when they had lived, now he thought, . . . as it might have been in some old Garden of Eden. . . . In the past, there had been only a little group of people, scarcely more than an overgrown family. In the future, there would be the State. . . . And now the first act of the State, its originating function, had been to bring death. (1949, p. 247 in the Ace edition)

Chad Oliver, an anthropologist, understandably provides the most knowledgeable and integral examples of fiction which incorporates and elaborates upon culture concepts. In the novel *Shadows in the Sun* (1954a), Oliver extrapolates both from the methodology of cultural anthropology and the concept of culture patterns. The narrative concerns the experiences of the hero (a cultural anthropologist) as he analyzes the data obtained from a community study of an American small town. The data do not produce the expected correlations; there seems to be something strange about the culture which was not detectable during the field work. Gradually the explanation emerges: the town is populated solely by aliens from another planet who have slowly bought up the property and settled there in order to have a base camp on earth. They have successfully posed as earthlings until culture-pattern analysis unmask them.

Oliver's short story "Rite of Passage" (1954b)

also focuses on the concept of cultural configuration. Three survivors of the crew of an interplanetary exploration expedition, one of them the official anthropologist, land on a planet of another solar system. They are welcomed by the inhabitants, whose culture is apparently primitive and pastoral. After a brief sojourn among the Nern, during which the anthropologist is taught the language by the village shaman, the other crew members are eager to introduce the basic elements of technology. The anthropologist, however, deduces correctly that the Nern have eschewed technology by deliberate option, by "editing" their culture "down to essentials," i.e., the goal of "survival with maximum integration, cohesiveness of function, individual fulfillment, constant challenge, and peace" ([1954b] 1966, p. 282). They are "masters of the culture process," experts at introducing their own ideas in other cultures at a distance through psychology, hypnosis, and adroit appeals, at turning enemies into allies, and destroying them.

Linguistics is also a favored theme in anthropological fiction, particularly those aspects that deal with the relationship of language to culture. What fascinates writers of social science fiction is the thesis that language can control behavior. Perhaps the best example is in 1984, a novel which is primarily political science fiction. *Newspeak*, the language devised by the totalitarian regime described by Orwell, is one of the state's major instruments of thought control. Its purpose, as Orwell describes it in the appendix to the novel, is "not only to provide a medium of expression for the world-view and mental habits proper to the devotees of Ingsoc [English socialism], but to make all other modes of thought impossible" (1949, p. 246 in the 1961 edition).

Jack Vance's *The Languages of Pao* (1957) is another example of linguistic fiction. The story, set far in the future, centers on the thesis that language creates cultural values and thus can be deliberately used to create new social systems. The ruler of an "acquiescent" society on the planet Pao obtains technical-assistance experts from another planet to help him defend Pao against its enemies. The visiting superscientists are anthropologists and linguists, and they transform Pao into an aggressive caste society by creating and inculcating three separate languages: one for the military, with a syllabary "rich in effort-producing gutturals and hard vowels"; one for the industrialists and technicians, with an extravagantly complicated but logical grammar and "elaborate rules of accordance"; and one for the traders, with "emphatic

number-parsing, elaborate honorifics . . . to facilitate ambiguity, a syntax of reflection, reinforcement and alternation to emphasize the analogous interchange of human affairs" ([1957] 1958, p. 57).

Another subdiscipline of anthropology—archeology—has provided inspiration for writers of the science fiction school. The reconstruction through archeological techniques of vanished civilizations on distant planets has introduced a new twist to the so-called space operas of an earlier period. The examples are numerous and endlessly fanciful. In fact, the physicist-biochemist Leo Szilard wrote a parody that seems aimed both at archeologists and archeological fiction. Entitled "Grand Central Terminal" (1952), it solemnly describes the efforts of "alien" archeologists from space to reconstruct the image of earth culture from the ruins of the station and its public facilities.

**Sociology.** The pervasive influence of the concepts and terminology of sociology is reflected in works of social science fiction that explore new forms of social stratification or new mechanisms of social control or which are imaginative projections of such present-day social pathologies as overpopulation, drug addiction, organized crime, juvenile delinquency, and the manipulation of behavior through the mass media.

Although a popular form of sociological science fiction is the dystopia, in the tradition of 1984, both the character of the menace and the objectives of the protest are different from those described by Orwell. The contemporary sociological version of the dystopia is concerned not with the problem of oligarchy but with the ultimate triumph of a mindless mass mentality. Two novels, *The Thirty-first Floor* by the Swedish writer Peter Wahlöö (1964) and *Fahrenheit 451* by the American Ray Bradbury, are cases in point. Both novels describe static, egalitarian societies of the future that are dominated by a mass culture, in which independent thought is stifled and conformity to the bland average in behavior is enforced. The values of these societies are expressed and promulgated by the homogenized mass media. Reduced to the lowest common denominator of emotional and intellectual appeal, the press and television eschew all controversy, offend no one, and level all aspirations to a moronic hedonism. The institutional means of control is censorship. In Wahlöö's world the censorship is unofficial, unobtrusive, but nonetheless pervasive. Private enterprise and government are intertwined and opinion is controlled by a democratic combine of the press, the trade unions, and the political parties. A vast publishing

concern shields the individual's peace of mind and security ([1964] 1967, p. 37) from all information about discontent (suicide, deviance, drunkenness) or negative frightening realities (crime, pollution, overcrowding). It is "the majority of people . . . [who] act as censors" (*ibid.*, p. 175); society protects itself. In Bradbury's dystopia, censorship is overt: the agents of control are the firemen, whose assigned duty is not to put out fires but to destroy books, which are outlawed as incendiary threats to the mass mentality (451° F. is the temperature at which book paper is said to burst into flame). As the Firechief explains to the fireman hero Montag, who has begun to read clandestinely the books he is supposed to burn: "It didn't come from the Government down. There was no dictum, no declaration, no censorship to start with, no! Technology, mass exploitation, and minority pressure carried the trick" (1953, p. 53). But the social process became an ideology:

We must all be alike. Not everyone born free and equal, as the Constitution says, but everyone *made* equal. . . . then all are happy. . . . Don't give them any slippery stuff like philosophy or sociology to tie things up with. That way lies melancholy. Any man who can take a TV wall apart and put it back together again . . . is happier than any man who tries to slide-rule, measure, and equate the universe. . . . (*ibid.*, pp. 53, 56)

True to form, both Wahlöö and Bradbury exalt the rebel against the rationalized society. In *The Thirty-first Floor* a dissident editor, tricked with other intellectuals into collaboration with the "concern," threatens to blow up its headquarters. In *Fahrenheit 451* Montag joins the underground—people living in the hills and backwaters who also burn books but memorize them first. Each person in fact is a book ("I am Plato's *Republic*" is an introduction). In this way the oral traditions of man's preliterate past enable civilization to survive until a nuclear holocaust, beginning as the book ends, destroys the centers of anti-intellectualism.

In *The 10th Victim*, a humorous novel about the future by Robert Sheckley (1965), another social process is described. In the twenty-first century, a society sick of war has finally evolved a functional substitute for aggression: the legalization of murder through the institution of the Hunt. The Hunt is described as an international contest, in which participation is voluntary. In all the capitals of the civilized world, giant computers randomly select pairs of antagonists who are licensed as "hunter" and "victim." Prize money is awarded to the victors; the hunters and victims alternate roles until one of them reaches the limit of ten kills. Intended for

As a result of aggression the threat to other neighborhood  
is unknown whereas other neighborhood is not  
aggression, p. 20

Several developmental milestones in the child language domain indicate that the child is ready to learn a second language. These include the child's ability to understand a wide range of language input. Most infants learn to understand and discriminate between all the linguistic forms that are presented to them in the first 12 months of life. They begin to understand the meaning of words and to use language to communicate with others. They also begin to understand the meaning of words and to use language to communicate with others. They also begin to understand the meaning of words and to use language to communicate with others.

[illegible]

Two kinds of very important information may be obtained from the analysis of the following statements. When the number of all items is known, it is possible to determine the value of the items. The value of the items is the sum of the items. The value of the items is the sum of the items.

[illegible]

A third source of the gap is differences in the way that individuals in the two countries interpret the question. In the United States, the question is interpreted as asking for the number of people who are currently in the military. In the United Kingdom, the question is interpreted as asking for the number of people who have ever served in the military.

On the other hand, it is also true that the government has been successful in its efforts to control inflation and stabilize the economy. The government's policies have helped to bring about a period of relative stability and growth.

**Comments:** This book is an amazing glimpse into the world of a young woman, performed in a clear, accessible manner. It is the only volume of the series that speaks of her childhood, as *The Glass Heart* is devoted to her years as a sheltered, pampered princess, and *An Extraordinary Girl* is devoted to the turbulent adult years, and the journey toward peace, wisdom, and forgiveness. *Unsettled* is the only book in the series that speaks of her years as a sheltered, pampered princess, and *An Extraordinary Girl* is devoted to the turbulent adult years, and the journey toward peace, wisdom, and forgiveness. *Unsettled* is the only book in the series that speaks of her years as a sheltered, pampered princess, and *An Extraordinary Girl* is devoted to the turbulent adult years, and the journey toward peace, wisdom, and forgiveness.

### 1 THE HISTORY OF THE CONCEPT OF SOCIAL STRUCTURAL ANALYSIS

Edmund R. Leach  
Stanley H. Udy, Jr.

#### THE HISTORY OF THE CONCEPT

In academic work the evaluation of concepts depends upon their use by specialists. In the decade following World War II the concept of "social structure" became extremely fashionable among social anthropologists and at times attained even extreme prominence. It should be apparent to anyone who has followed developments of recent years that the concept has not been served by pursuing all these ramifications of usage. Instead, this article evaluates the meanings of the concept adopted by George Murdock in America, A. R. Radcliffe-Brown and various of his followers in Britain, and

Claude Lévi-Strauss in France. The usages of other writers may be considered as modifications of one or other of these relatively extreme positions. Although nationality is relevant here, it is not decisive; there are British anthropologists whose position is close to that of Lévi-Strauss just as there are Americans whose postulates are very similar to those of Radcliffe-Brown, but "structuralist anthropology" has a different connotation in France and in Britain, and the two meanings should not be confused.

Early uses of the concept. Although the fashionable use of the term is a post-1945 phenomenon, the concept of "social structure" has a long history, which may be briefly reviewed. In its original English meaning the word "structure" referred to building construction, but by the sixteenth century it was also being used to refer to the interrelations between the component parts of any whole. It was in fact widely used in this sense in anatomical studies, which were in active development at that period. Its further extension from anatomy to sociology, though delayed for several centuries, was a logical corollary of the very general use of organic analogies by political philosophers. Hobbes does not actually use the expression "social structure" in his *Leviathan*, but his conception of the state as an artificial organism, in which the function of each component institution and office holder is carefully distinguished, is one to which the term might very well have been applied even in the seventeenth century. The explicit idea that the study of social structure should be an objective for sociological enquiry seems to be due to Spencer (1858), who refers to "the Inductions of Sociology—general facts, structural and functional as gathered from a survey of societies and their changes."

The fact that Spencer brought the terms "structure" and "function" into direct association shows that he had an anatomical image in mind. This image appears again in the work of Durkheim, who was the source of Radcliffe-Brown's ideas. As early as 1910 the latter gave lectures on Durkheimian sociology under the title "Social Structure." Provided that we accept the organic analogy, there is no difficulty about understanding what these authors mean. Society is treated as a kind of living creature, the parts of which can be dissected and studied. The "social structure," then, is the mesh of mutual positions and interrelations in terms of which the interdependence of the component parts may be described, the "function" of any part is the way it operates so as to maintain the total system in good health. But as soon as we ask such questions as Is society really an object

ism? Where do we discern the boundary between one society and the next? How do we distinguish between a society that is in good health and one that is in a pathological condition?, the extreme artificiality of the model becomes apparent.

A less clearly defined strand of thought, which is free of organic overtones, is to be discerned in early Marxist literature. This is relevant for anthropology because of the close dependence of Engels (1884) upon Morgan (1877). Marx (1859) had written of the relations of production as constituting "the economic structure (*Struktur*), the real basis (*Basis*) on which is erected a juridical and political superstructure (*Oberbau*) and to which correspond the forms (*Formen*) of the determined social conscience." Marx's metaphor here is plainly that of a building, not of an organism, but the notion of structure is not sharply distinguished from a variety of other concepts. Elsewhere there are references to political, juridical, religious, and philosophical systems—in contexts where the word "system" is indistinguishable from the above uses of "structure," "superstructure," and "form" (Lefebvre 1962). More recently, sociologists have added such variants as "infrastructure," "macrostructure," "microstructure" on an apparently arbitrary basis. Engels (1884) specifically refers to Morgan's "Stage of Savagery" as one in which "the social structure is based on ties of consanguinity," but we need not suppose that he had any very clearly defined concept in mind, such expressions as "social order," "social system," or "social form" would have served just as well. On the other hand, if one were to seek a candidate for the first anthropological work which may be considered a "study of social structure" (in any of the three senses under discussion), the most obvious candidate is certainly Morgan's work (1871), where the title word is *Systems*. The terms "system" and "structure" are not always synonymous in anthropological writing, but they are often indistinguishable.

Murdock. The meaning which Murdock attaches to the expression "social structure" may be gathered from the items listed below. His principal concerns are the ethnographic facts and the taxonomic classification of societies on the basis of manifest, readily discernible characteristics. The Human Relations Area Files, located at Yale, which were originated by Murdock and which have remained his principal research tool, are an attempt to compare societies systematically by analyzing written source materials (of very varied quality and origin) according to a strictly uniform procedure. It is presupposed that the tribal names which appear in anthropological monographs correspond

to fixed, readily distinguishable social entities (societies, tribes, cultures), which are fully described by listing the sum of their attributes. Murdock has drawn up a list of such possible attributes (Yale University 1938), and the immediate purpose of the Area Files (HRAF) analysis is to determine whether each listed attribute does or does not occur in the particular "society" under investigation. The taxonomy established by Murdock (1949) depends primarily on varieties of kinship organization. Insofar as Murdock uses an organic analogy, it is that of a dissected model laid out in a showcase, there is no attempt to envisage society as a living entity capable of growth. The taxonomy is based upon statistical correlation rather than functional analysis. The similarity of society A to society B is a factor measured by the number of instances in which the two societies share the same attributes as measured by the HRAF scheme of analysis. The ultimate objective is historical. In botany, Linnaeus' taxonomy, based on classification by attributes, was later adapted into a scheme for tracing lines of evolution on a phylogenetic basis. Murdock claimed that his social taxonomy could likewise lead to evolutionary inferences (1949, chapter 8 and appendix). Critics reject the view that social aggregates are closely comparable to botanical species and argue that Murdock's view of cultural attributes is misleading. Concepts such as "patrilineal descent," "matrilocal residence," and so forth do not refer to characteristics which are present or absent in any clear-cut way in any particular case. Murdock's use of statistics shows that he considers each of his listed cultural attributes intrinsically independent of any other. This is completely at variance with the assumptions of the functionalist anthropologists, who presuppose an intrinsic interdependence between the parts of the whole.

Despite his use of the term "social structure" in book titles, Murdock's attitude has been ambivalent. He denigrates the concept as "static" and "sterile" (1955). He argues that emphasis on "structure" should be replaced by an emphasis on "process"; "The Linnaean system," he remarks, "only became something living after Darwin had discovered the process of variation and natural selection." Vogt (1960) makes a similar distinction, contrasting the "static" notion of structure (which he sees as a characteristic preoccupation of British anthropologists) with the "dynamic" notion of process favored by American scholars. It is not clear to the present writer how "social process" in Vogt's sense can differ from "history," and it appears that all those who write in this manner are in some meas-

ure historical determinists who believe that "laws" of social change can be discovered if we only look hard enough. The assumption that synchronic studies are necessarily "static" while diachronic studies are "dynamic" is not borne out by the facts, and the identification of this antithesis with a contrast between structure and process is meaningful only if structure is restricted to the formal and static taxonomic sense adopted by Murdock. For example, Fortes' "Time and Social Structure: An Ashanti Case Study" (1949) and Goody's collection of essays (1958), which derive from it, are all based on synchronic studies; they are all studies of social structure (in the British but not in Murdock's sense), but none of them is concerned with static phenomena.

**Radcliffe-Brown and the British school.** Murdock's use of the word "structure" implies either a building analogy ("society is an assemblage of independent bricks") or a dead organic model dissected for demonstration. In contrast, Radcliffe-Brown presumes that society may be compared to a living organism or a working mechanism. For Radcliffe-Brown, a society has a life of its own: it is not an object so much as a creature, so that the study of structure—that is, the interdependence of the component parts of the system—is indissolubly linked with the study of function, or how the component parts of the system "work" in relation to each other and to the whole.

Radcliffe-Brown's explicit formulation of this view and its application to anthropological studies are post-1931 developments. Radcliffe-Brown's *A Natural Science of Society* (1957) shows how he was thinking about these matters in 1937, when it was written. Bateson (1936) illuminates directly the parting of the ways between the cultural analyses of Malinowski and Benedict, on the one hand, and the structural view favored by Radcliffe-Brown, on the other. The structuralism of Radcliffe-Brown was developed as a reaction to the lack of precision shown by Malinowski in his handling of the concept of culture. Warner's *A Black Civilization* (1937), written under Radcliffe-Brown's tutelage, is the earliest monograph which is unambiguously structuralist in style in this sense.

Although Radcliffe-Brown's views of social function depend upon a holistic view of social structure, his British followers have not, in general, concerned themselves with the analysis of total working systems. Radcliffe-Brown himself was engaged in comparative work and theoretical generalization, and he encouraged his followers to concentrate on those aspects of a social system which display clear-cut formal characteristics and which

reflect to a minimal degree the interplay of personal rivalries. A characteristic sample of such studies may be found in Radcliffe-Brown (1924–1949), Fortes and Evans-Pritchard (1940), Radcliffe-Brown and Forde (1950), Evans-Pritchard (1940), and Fortes (1945). The authors concern themselves with only one formal aspect of society at a time—political structure, kinship structure, ritual organization, as the case may be. They display this system as a set of rules (jural obligations); they discuss the mutual interdependence of the rules and the fit between the society and its environment (ecology). But there is a tendency to play down any discrepancy between rule and practice. As a consequence of this, these studies show a marked neglect of economic organization.

**Firth and other British structuralists.** In contrast, other British writers such as Raymond Firth and A. I. Richards took over functionalist ideas (in a rather different form) from Malinowski but rejected Radcliffe-Brown's thesis that a system of jural regularities—a formal "structure"—may always be discerned behind the day-to-day operations of social life that an anthropologist observes in the field. It is notable that Firth and Richards pay much greater attention to economics than do the British structuralists and have consistently stressed the importance of the individual acting in his own interest as against the importance of Radcliffe-Brown's "social person," whose actions are fully defined by the rules which pertain to his social situation. A terminological detail calls for attention here. For Radcliffe-Brown and his followers the expression "social organization" is, in most cases, a synonym for "social structure," but Firth has for many years used "social organization" as a polar concept by which he seeks to emphasize the discrepancy between what actually happens and what a formal study of the rules might lead us to expect (see Firth 1964). The two viewpoints are complementary, and the tendency during the last few years has been for British writers to move closer to Firth's position (e.g., compare Forde 1950 with Forde 1963; both papers discuss the same aspects of Yakö social structure, but the former, written directly under Radcliffe-Brown's influence, lays far more stress on the formal aspects of the rules as distinct from their practical application).

**Weberian theory.** Over the years, British structuralism has been considerably modified by the assimilation of ideas derived from the sociology of Max Weber into a theoretical framework which was originally derived from Durkheim. Linton (1936) seems to have been the first anthropological author to make explicit use of the Weberian con-

cepts of status and role, although it seems possible that Linton himself was influenced by Radcliffe-Brown (then teaching in Chicago). A full-scale development of Weberian role theory as a tool of anthropological analysis is to be found in Nadel's *The Theory of Social Structure* (1957). Other Weberian concepts which have been extensively utilized by British structuralists are given below.

(1) There is the notion of "ideal types," which has sometimes been assumed to depend upon a discrimination similar to that by which Firth distinguished social structure from social organization. (2) There is the threefold typology of "traditional," "bureaucratic," and "charismatic" leadership. Weber's notion of the charismatic leader has proved particularly rewarding in the analysis of such phenomena as Melanesian cargo-cults, and an extensive literature discusses how far the structure of government in African states of the "traditional" type may be compared with or distinguished from "rational bureaucracy" of the western European type as understood by Weber (e.g., Fallers 1956). (3) Weber's concept of *Verband* was translated into English as "corporate group," thus suggesting an exact equivalence with the concept of "corporation," which has a sophisticated technical significance in English jurisprudence and which became assimilated into the language of British anthropology through its treatment by Maine (1861). In a penetrating summary of a large body of writing, Fortes (1953) pointed out that a crucial characteristic of the British structuralist studies of the interplay of political organization and kinship was that they treated unilineal descent groups (clans, lineages) as corporate groups in Weber's sense and that on this account a substantial body of Weberian theory became directly applicable to anthropological analysis.

It is notable that anthropological structuralism in the British sense has achieved its most convincing results when applied to social systems in which a segmentary structure of unilineal descent groups provides the over-all framework within which political activity takes place. In societies which lack unilineal descent groups and where, consequently, the Weberian categories are harder to apply, structuralist analysis has proved markedly less successful. As a by-product of this failure of theory, some writers have tried to prove that societies which lack unilineal descent groups are really just the same as those which possess them (Davenport 1959), the apparent object of this exercise being to show that Weberian categories can be applied with success even to "nonunilineal" descent groups. In the present writer's opinion this is a fallacy.

The ensuing debate has led to a clearer definition of various standpoints. The following summarizes what seems to be the present position of Fortes: Society is to be viewed as a system of corporations in Maine's sense. The corporations may be perpetual groups (corporations aggregate) or perpetual offices (corporations sole). Each such corporation has associated with it a set of jural rules which specify *inter alia* what the corporation possesses (its "estate"), who the members are ("the principle of recruitment"), how leadership within the corporation is exercised, what the formal rights and obligations of the corporation as a whole are vis-à-vis other like corporations, what the formal rights and obligations of the subunits of a corporation are vis-à-vis one another. The ultimate units of any such segmentary system are individual office holders, but it is important to distinguish the office from the individual who holds it. An office is, in principle, immortal; the holder is not. The individual in the course of his lifetime moves from office to office and always holds a variety of different "offices" simultaneously. The rights and duties of a particular office can be uniquely specified, but the rights and duties of a particular individual will depend on circumstance and will normally entail inconsistency. Thus an individual who holds office as head of a university department and is also the owner of a particular residential house and the father of a family will have rights and duties in respect to each of these statuses, but it may or may not be possible for him to fulfill all three roles with equal adequacy.

A full description of the social structure would entail an analysis of all the rights and obligations which link all the offices and corporations in the system—a task which would be plainly impossible but which can be carried out piecemeal in a partial way. The anthropologist's focus of interest is not in this structure as such but in "the way it works"—that is, in the perception of the way in which living human beings, who are all the time being born, growing older, and dying, *pass through* an ordered system of offices.

At a beginning level of analysis the system of offices is unchanged by the passage of individual office holders through the system, and it is at this level that Fortes has concentrated his own work (1949). At the next level of analysis "social change" results from the fact that individual office holders modify the rules pertaining to the offices which they occupy. In Fortes' view the sociological analysis of "change" in this sense is a matter for the future and may prove impossible.

Other British writers have tried to evade this

limitation, and recently there have been a number of attempts to bring the dimension of historical time within the scope of structural analysis while avoiding the pitfalls of historical determinism. Leach's *Political Systems of Highland Burma* (1954) was an attempt of this kind, which presents Kachin political ideology as a structure of persisting verbal categories and argues that historical change in the empirical society results from a re-interpretation of existing categories rather than from a change in the structure of ideas.

Fortes' interest in the way individuals move into and out of social office links his work with that of Gennep (1909), and, despite the greater importance attached to ideas deriving from Weber, the influence of early twentieth-century French sociology on the work of British "structuralist" anthropology remains very strong. As a consequence, despite differences of terminology and orientation, French and British ideas about social structure cannot be fully distinguished.

Lévi-Strauss and the French school. The mathematical idea of "structure," which is also that employed in "structural linguistics," is somewhat different from that of either architecture or biology. The emphasis here is upon the transformability of a relational set rather than upon the quality of the relations as such. If a piece of music—originally in the form of a sheet of printed notes—is played on a piano, recorded on a phonograph record, transmitted over the radio, and finally played back to an auditor, the music passes through a whole series of transformations—it appears as printed notes, as a pattern of finger movements, as sound waves, as modulations of the grooves on a piece of bakelite, as electromagnetic vibrations, and so on. However, something is common to all these manifestations. That common something is their structure. This mathematical idea is abstract and very general; it includes the biologist's notion of structure as a special case. The analogous notion of "social structure," when derived from the mathematical concept, has likewise more general, more abstract uses than when it is based on an organic analogy. Lévi-Strauss's view of structure has been taken over more or less directly from linguistics, and it is because of this that his arguments often appear highly abstract when compared to the relatively empirical analyses of British structural anthropologists, whose ideas ultimately derive from biology through the thinking of Radcliffe-Brown. Radcliffe-Brown conceived of the task of social anthropologists as that of establishing a kind of Linnaean taxonomy of functioning social systems. In such a taxonomy the difference between one

society and another would be one of structure, but this structure was a readily describable empirical characteristic of the system. In Lévi-Strauss's analysis, on the other hand, interest in structure comes to the fore only when one system is contrasted with another. Lévi-Strauss is interested in how far empirical systems correspond (or fail to correspond) with the theoretically possible transformations of a single (mathematical) structure; his structures thus start out as "models" rather than as empirically observed facts. For example, it is possible to imagine, as an ideal type, a society which has a strictly unilineal descent system and a strictly "unilocal" residence pattern. This gives us two binary variables—descent, which is patrilineal ( $P$ ) or matrilineal ( $M$ ), and residence, which is virilocal ( $V$ ) or uxorilocal ( $U$ ). With these limitations, we have four possibilities (or classes):  $P + V$ ;  $M + U$ ;  $P + U$ ;  $M + V$ . Actual societies do not fit tidily into categories of this kind, yet a great many actual systems can be approximately sorted in this way. If this is done certain facts emerge. The distribution is not at all random. Societies of class 1 are common, of class 4 less common, of class 2 very rare, and of class 3 virtually nonexistent.

We are then led to consider just why such distributions should be nonrandom, and this may lead us to fundamental insights into factors which affect all human societies and not just societies of a particular taxonomic type.

In a Radcliffe-Brown analysis, "the structure which persists" is the structure of a particular society associated with a particular culture and a particular geographical locality; in a Lévi-Strauss analysis, "the structure which persists" is an attribute of human social organization as such; we can come to recognize the nature of this structure only when we build up a generalized model from radically contrasted empirical examples. As a case in point, Lévi-Strauss (1963) has compared the stereotype of Australian aboriginal society with the stereotype of Indian caste (see Table 1).

Lévi-Strauss's argument is that in the Australian context all the items in the left-hand column are structurally and functionally interdependent and in the Indian context all the items in the right-hand column are similarly interdependent, but since the items listed on the right are the mirror inversion of those listed on the left, the structure represented by the right-hand column is really the same structure as that represented by the left-hand column. The right-hand column is generated from the left-hand column by applying a single transformation rule—the structure "remains the same," in the same

Table 1

Australian society	Indian society
In Australia the social unit is a "horde," which is exogamous.	In India the social unit is a "sub-caste" ( <i>jati</i> ), which is endogamous.
Hordes are distinguished as totemic groups, totems being categories of nature (animals, plants).	Subcastes are distinguished as occupational groups, occupations being categories of culture (potters, ropemakers, drummers, etc.).
The activities of totemic groups are group activities sanctioned by myth and consist of the ritual creation of animals (things of nature).	The activities of caste groups are individual activities based on real knowledge and consist of the rational creation of artifacts (things of culture).
Magical totemic increase ceremonies rest on an ideology that totemic groups should supply each other with food just as they supply each other with women.	Ritual attitudes to pollution have the consequence that a subcaste is a commensal group as well as an endogamous group. The exchange of food across subcaste boundaries is prohibited.
In all other respects the division of labor depends only upon sex and age. Horde groups and totemic groups are not occupationally differentiated.	Since subcastes are differentiated by occupational specialization they are economically interdependent.
Thus the larger society is united by intergroup transactions involving the interchange of objects of nature (women and food).	Thus the larger society is united by intergroup transactions involving the interchange of objects of culture (artifacts and occupational services).
Horde groups and totemic groups are of intrinsically equal status.	Subcastes are of intrinsically unequal status.

Source: Based on Lévi-Strauss 1963.

sense as a square remains the same when we rotate it through 90 degrees or an algebraic equation remains the same when we change all plus signs into minus and minus signs into plus. Lévi-Strauss's procedures for discriminating between relevant and irrelevant evidence are no doubt arbitrary, but so are those of his British colleagues, and his demonstration that patterns of "structure" of this kind exist in the ethnographic data poses problems of fundamental sociological significance.

**Assessment.** I have outlined three different uses to which the concept of social structure has been put by leading contemporary anthropologists. The value which we place on these different usages will depend upon our objectives. The Murdock usage and the Radcliffe-Brown usage are clearly to be preferred if our prime interest is typological and taxonomic, while those who set themselves the ambitious objective of discovering human universals will be more attracted by the higher-level abstractions which Lévi-Strauss has brought into

the discussion. It deserves note, however, that none of these theorists has as yet dealt at all adequately with the time dimension in social affairs.

Whichever way we approach the concept of structure, it entails the notion of persistence. In Fortes' treatment, the time of history and the time of the individual life cycle are distinguished. The structure of social units is conceived of as permanent relative to the life span of the individual members of society who pass through the system. Fortes would not claim that social structures in his sense are changeless but only that they are relatively changeless. For his purposes, change in structure is a phenomenon of history and as such lies outside sociological analysis. Lévi-Strauss, on the other hand, has tried to integrate his scheme with a kind of Neo-Marxist-Hegelian dialectic. The emphasis on binary contrast, which permeates the "structuralism" of Lévi-Strauss and his associates in a very radical way, is a direct borrowing from the structural linguistics of the Prague school and is closely linked with Jakobson's use of the notion of "distinctive features." It also seems to tie in with the *contrast theory of meaning*, which is one of the doctrines of the Oxford school of linguistic philosophy. The essence of the argument is, roughly, that "we can recognize a thing for what it is by seeing what it is not"; thus the structure of any set is that which is common both to the set and its inverse (cf. the horde/subcaste example above). This can be given a Hegelian twist by identifying the structure with the "synthesis" which derives from (but is already implicit in) any "thesis" when viewed in conjunction with the "antithesis" which it generates. It is not at all clear to the present writer just how Lévi-Strauss relates this potentially historicist argument to his structural models. Sometimes he seems to be saying simply that contrasted empirical examples of social systems are best understood as different manifestations of a single model structure; at other times there is a suggestion that the different manifestations are viewed as a dialectical sequence, each empirical type serving to generate its own antithesis. By this argument societies which are contrasted manifestations of the same structure should be found distributed in adjacent territorial areas in a synchronic dimension and in the same territorial area in a diachronic dimension. Pareto's ideas about a "moving equilibrium" are not very different from this. Leach's *Political Systems of Highland Burma* (1954) can be considered as an attempt to test out this argument in terms of concrete ethnohistorical materials.

Structuralism in linguistics has run into the same time-scale difficulties as structuralism in

social anthropology, and it may be of interest to see what has happened in this neighboring field. It has lately come to be emphasized that a verbal utterance can never be a synchronic event. It starts at the beginning and progresses to the end. The form of the utterance is not, in general, completely predetermined by its beginning; it is "generated" as the utterance progresses as a response to grammatical rules which are applicable or not applicable depending upon the developing sequence. The grammatical rules are like the rules of a game: they do not determine what is said; they merely delimit what is a permissible choice at any particular point in the sequence. They specify what is possible and also what is not possible, but between these limits they allow freedom of choice. The work of the mathematical economists has been developing in a rather similar way: progressions of events through time are coming to be thought of as delimited by qualified rules (as in a game) rather than "determined" in an historicist sense. This kind of application of game theory and its derivatives disposes of the notion that structure is, of necessity, a static synchronic concept. A game of chess is a sequence in time, and no individual move in the sequence is predictable, yet it is plain that the sequence as a whole is "structured" in a quite formal and easily describable way. The rules of chess are specific and not generative, but we are familiar enough with types of games where the rules themselves change according to circumstance—e.g., a dice game which includes the rule "player who throws a six has two extra throws." Some British anthropologists are already disposed to make their descriptions of social structure in terms of sets of rules defining the interdependent rights and obligations attaching to sets of offices. To start thinking of such rules as being of the generative kind would not call for any very drastic modification of established conventions. Barth (1959; 1966) is one of the few anthropologists who has so far made some tentative exploration of this idea. In the view of the present writer it may prove a fruitful line of development.

## II

### SOCIAL STRUCTURAL ANALYSIS

The concept "social structure" is, paradoxically, so fundamental to social science as to render its uncontested definition virtually impossible. Basic concepts in particular seem likely to suffer from this difficulty, since their primordial character demands that they provide an effective link between the field of inquiry and the particular approach, or even the personal philosophy, of the individual scholar. Various controversies, both apparent and real, are thus especially likely to surround the use of such concepts. In the case of "social structure," some of these difficulties are purely terminological and are, hence, more easily resolved than may

appear possible on the surface. Others derive more fundamentally from disagreement over the basic philosophical assumptions appropriate to social research. And still others reflect substantive theoretical problems, which seem likely to persist even when there is agreement over terminology and basic philosophy. Before one can proceed to analyze social structure in detail, one must confront certain basic issues arising from these three areas of controversy.

**Terminology.** Despite some contention to the contrary, I would hold that terminological problems are relatively easy to solve, since there is more agreement among sociologists and other behavioral scientists about concepts than about what words should be used to designate them. Virtually every general approach to social behavior involves some or all of the following five conceptual distinctions as actual or potential distinct loci of variation:

- (1) An *individual* component, i.e., some conception of personality or aggregated characteristics of individual personalities.
- (2) A *group* component, i.e., a set of variables essentially referring to various aspects of the process of social interaction among people.
- (3) A *morphological* component, i.e., a set of variables pertaining to the spatial-temporal arrangement of individuals and the physical size of groups.
- (4) A *systemic* component which focuses on the properties of interrelationships among activities as such, independently of the people performing them, generally treating such activities as social roles.
- (5) A *cultural* component comprising ideas (norms, values, beliefs) which are learned and shared by people and are transmitted symbolically from person to person.

As we shall see presently, different philosophical and theoretical viewpoints yield different orderings of relative emphasis on these five components and, indeed, sometimes result in wholly eliminating one or another of the components from effective consideration. From a purely definitional standpoint, the question of what one means by "social structure" thus reduces to the question of how many and which of these five conceptual components one wishes to denote by the term. Since we wish to compare, and to some degree synthesize, various points of view, we shall define "social structure" very broadly as the totality of patterns of collective human phenomena that cannot be explained solely on the basis of human heredity and/or the non-human environment (compare Levy 1952, pp. 8-17). This definition includes all five aspects, allows

for interrelations among them, and thus provides a context for a comparative discussion of current approaches.

### Philosophical assumptions

Certain basic philosophical questions raised principally by the "structuralist" cultural anthropologists bear on the question of the relationship of models to social structure (Lévi-Strauss [1958] 1963, pp. 277-323). Everyone presumably agrees that the twentieth-century scientist, as opposed to his nineteenth-century counterpart, is no longer trying to "discover reality" but, rather, is seeking to understand observations by imposing different kinds of order on them in the form of various models, exploring the implications of each, and accepting one model as opposed to another on pragmatic grounds. The structuralist position in effect extends this argument by observing that ordinary people are subject to the same epistemological limitations as are scientists. According to this view, any discussion or thought of social structure by anyone implies that he is constructing and using models, which we shall term "folk models" to distinguish them from the analytic models constructed by the scientist (Anderson & Moore 1960). Folk models thus constitute an important cultural element of social structure; some examples would be forms of games and patterns of responses to questions, as well as language itself. The formal properties of folk models are, furthermore, susceptible to study and are capable of yielding important insights into social structure through such procedures as, for example, "componential analysis" (Goodenough 1956).

Few social scientists would disagree with this position as stated so far. To be sure, it begs the question of the relative explanatory importance of folk models as opposed to other aspects of social structure under given circumstances, but such a question is presumably a fruitful one which can in principle be answered through empirical research. However, the argument usually does not stop at this point but frequently proceeds to combine with the foregoing an essentially phenomenological view of social reality. As a result, folk models emerge, not simply as one important component of social structure but as the totality of social structure itself. The study of social structure thus becomes no more and no less than the study of folk models (see Lévi-Strauss [1958] 1963, p. 279). This perspective leaves us, however, with the problem of the relationship between folk models, on the one hand, and analytic models constructed by the scientific observer, on the other.

It must be said that some confusion occurs in the structuralist literature as a result of a frequent failure to make this distinction explicit. Once such a distinction is made, however, it becomes apparent that these two types of models are very likely to be quite different; indeed, if they were not, the value of social science itself would be highly questionable. And not only can the social scientist construct analytic models based on his analysis of folk models, but he can also construct analytic models of other social phenomena that are not necessarily reflected in the cultural system at all, such as certain morphological patterns. In order to maintain a consistently phenomenological viewpoint in the face of such possibilities, the structuralists are obliged at this point to assume that scientific models have latent cultural existence as "unconscious" folk models (*ibid.*, p. 281).

It is certainly possible, in principle, to proceed in this manner, but one may reasonably question the value of so doing. If one is concerned primarily with the analysis of the formal properties of symbolic systems *per se*—as are, in all fairness, most structuralists—the difficulties of this mode of procedure are not great. But where the analysis requires any investigation of latent behavioral or morphological characteristics, the attempt to maintain a consistently phenomenological viewpoint would seem to involve many unnecessary complications. Pragmatically, the same results could be obtained more easily by merely assuming such behavioral and morphological characteristics to be external to the cultural system and raising purely empirical questions regarding their relationships to it. Furthermore, divesting the structuralist approach of phenomenology does not result in stripping it of its genuinely valuable contributions: that it calls attention to the inevitability of model construction in the study of social structure and that it identifies folk models as an important component of cultural systems, in the process drawing particular attention to the relevance of linguistic analysis (Anderson & Moore 1960; Dumazedier 1964; Jaeger & Selznick 1964; Osgood et al. 1957). Moreover, such divestiture reveals a very important question that otherwise remains confused or obscured—the question of the importance of folk models, relative to other patterns of social phenomena, as sources of theoretical explanation. The problem of the relationship, under various conditions, of folk models on the cultural level to other patterns manifest on the morphological, systemic, group, and individual levels of social structure is a matter for empirical investigation, the answer to which can hardly be assumed away or defined out

of existence. Thus I would accept the epistemological observations of structuralism but would stop short of a phenomenological position. This position leads to substantive agreement with the structuralists that folk models, conceived as part of the cultural component of social structure, are indeed important; however, it also raises the question of the relative importance of such models under specified conditions as a matter for empirical determination.

### Theoretical problems

We may now turn to a discussion of actual theoretical issues as they center on two major questions: first, the relative ordering of, and general relationships among, the five aspects of structure previously indicated; and, second, the nature of the mechanisms of interrelationship.

**Divergent views of social structure.** As to the questions of ordering and general relationships, three basic viewpoints have been particularly important; I shall refer to them as the cultural, interactionist, and morphological positions, respectively. The *cultural* point of view emphasizes the explanatory primacy of culture as a system of ideas that are learned, shared, and transmitted by people who, in turn, are oriented to situations by virtue of the culture that they have learned. Situations thus evoke responses, culturally defined as role expectations, by virtue of which people find themselves interacting with one another, with the possibility of resultant morphological differentiation. The causal progression is from the cultural-individual aspects of the situation to the systemic aspects, to group characteristics, and, finally, to the morphological aspects of structure. The entire chain is not usually explicit; it is more common for this approach to stress the interrelationships of culture, personality, and social system, defining social structure as some combination of these elements, with group and morphological considerations viewed as somewhat ancillary. An essentially "theatrical" view of social structure emerges, wherein culturally defined systems of role expectations await the participation of people, and this participation either incidentally yields group and morphological characteristics or implies them as contextual constants.

It is impossible to discuss here all of the divergences of detail exhibited by different versions of the cultural approach; major instances would include "culturological" social anthropology (e.g., Kluckhohn 1953; Kluckhohn & Strodtbeck 1961; Murdock 1949), the phenomenological structuralism previously discussed, and the voluntaristic

theory of action applied to the analysis of social structure (Weber 1922; Parsons 1951; for a similar but somewhat different approach, see Nadel 1957; also see Kroeber & Parsons 1958).

In some respects both the interactionist and the morphological positions represent the obverse of the cultural approach, in that both postures either imply cultural and individual characteristics as contextual constants or view them as emergent secondary properties. In the *interactionist* version of social structure, people with highly generalized expectations about one another's probable behavior are taken as given and are morphologically presumed to interact with one another. From the ensuing reciprocal process of role taking and role playing, increasingly stable systems of role expectations emerge which, in turn, become generalized into superordinate systems of cultural norms. The causal progression is thus from group phenomena to systemic aspects and, finally, to cultural patterns (Blau 1964; Homans 1961; Mead 1934).

The *morphological* conception of social structure is essentially similar to the interactionist version, but it is more macroscopically conceived. It assumes a disposition on the part of people to engage in stable interaction relative to certain specified but highly generalized cultural expectations. Emergent systemic and cultural properties of the situation therefore depend on morphological structure, which, through variations in the numbers of people involved and their spatial and temporal relationships to one another, as well as to artifactual facilities, imposes limits on the possibilities of interaction capable of producing emergent characteristics (Cottrell 1955; Duncan & Schnore 1959; Durkheim 1893; Halbwachs 1938; Helm 1962; Schnore 1958).

These divergent viewpoints have, in turn, yielded apparently opposing conceptions of social structure. From the cultural standpoint, social structure emerges as an object of orientation comprising cultural and systemic elements in terms of which the actions of individuals, groups, and morphological entities occur or are directed. On the other hand, from the interactionist and morphological viewpoints, social structure has, by and large, been thought of as the totality of group and morphological patterns, with individual elements contained in the group patterns and with or without systemic components, depending on the particular version of theory. Cultural elements are viewed as essentially external, in either a contextual or an emergent sense, or they are for some purposes deemed irrelevant.

Two principal theoretical controversies have re-

sulted from this situation; one of these may be regarded as at least partially resolved, but the other is now only beginning to be fully explored. The first of these controversies is that of the cultural versus the interactionist versions of social structure. The key to the resolution of this problem lies in the development of the voluntaristic theory of action combined with the introduction of symbols into interaction theory. No adequate theory of social behavior now seems possible unless it explicitly recognizes some process of social learning. The symbolic interactionist position, in contrast with that at least implied by earlier "radical positivists," is that social interaction cannot be a purely physical process but, rather, involves reciprocal role taking and role playing with reference to a learned repertoire of relatively stable expectations (Mead 1934).

Approaching the same problem from the opposite pole, the voluntaristic theory of action seeks to remove the metaphysical cobwebs from transcendental idealism by arguing that the "force" of ideas on the social order is actually felt in an entirely empirical manner—through socialization and subsequent action, with inevitable reference to learned normative orientations (Parsons 1937, esp. pp. 77–82). Both positions, therefore, not only insist upon the existence of cultural components in social structure but also identify essentially similar ones: relatively stable sets of learned (and "learnable") normative expectations. The result is a more comprehensive view of social structure than either the cultural or the interactionist position alone provides; it includes four of the five components we have identified, excluding only morphological structure.

It is precisely this absence of morphological considerations that leads to the second major theoretical issue: the place of human ecology in current theories of social structure. The emphasis on elements capable of transmission through learning has at times led to stressing roles and norms to the exclusion of concrete people and things in physical space. The result can be a view of social action that is literally carried on by nobody anywhere. In this sense the achievement of a measure of integration between cultural and interactionist viewpoints has been something of a Pyrrhic victory; it has concomitantly involved—at least on the theoretical level—a gradual destruction of an earlier positivist unity of morphological and interactionist approaches (Durkheim 1893).

Among the consequences of this situation has been a tendency either to view demography and human ecology as distinct disciplines entirely sep-

arate from sociology, or to view many current theoretical developments as essentially irrelevant to social reality. Furthermore, since social research must necessarily start by observing people and things, another consequence of this line of theoretical development has at times been a virtually enforced lack of relationship between research and theory. This situation has led unavoidably to the existence of entire bodies of analytical and statistical operations that have no clear correlates in current theoretical thought and, consequently, to the viewpoint—which, in light of the highly operationalistic emphasis of modern science, is surprisingly widely accepted in sociology—that there exists something called "methodology" which is generically different from something else called "theory." The unreality of this dichotomy has made increasingly apparent the fact that the cultural, interactionist, and morphological approaches do not actually represent differing "schools of thought" so much as they represent emphases on different aspects of social structure; thus, any reasonably complete theory of social structure must explicitly confront the question of interrelationships among these different aspects.

**Causal mechanisms.** Curiously enough, the question of causal mechanisms in social structure has received relatively little explicit attention. Broadly speaking, two kinds of mechanisms seem to pervade the literature, more often implicitly than explicitly, deriving from the cultural and morphological approaches, respectively. The first type of mechanism, which we shall term *psychological*, assumes that individuals severally receive cues from the social environment which, when combined in their personalities with learned responses (culturally prescribed or not), result in actions that, when aggregated, constitute social-structural patterns. In contrast, the second type of mechanism, which we shall term *ecological*, seeks to explain behavior through a process of elimination by arguing that certain actions are impossible owing to limiting features of the situation; in other words, social action is patterned by virtue of the fact that it must occur within the confines of limiting conditions.

To some extent it is true that cultural theories of social structure tend to rest on psychological explanatory mechanisms and morphological theories to rest on ecological mechanisms, whereas interactionist theories historically have exhibited a shift in emphasis from ecological to psychological mechanisms. But this statement is, at best, only a partial approximation. For example, ecological mechanisms need not be limited to those involving

physical properties of a morphological nature; they can be extended to include cultural and systemic characteristics, as in "structural-functional requisite analysis" (Levy 1952) and in adaptive theories of social change. Wilson and Wilson, for instance, explicitly define "social structure" as "the systematic form of limitation by which eccentricities are checked and complementary diversities are preserved" ([1945] 1965, p. 49, italics added; also see Eisenstadt 1964). Actually, it is impossible to discuss one type of mechanism meaningfully without at least making some implicit assumptions about the way the other is operating in the situation. Thus the scope of any psychological mechanism is limited by what cues are in fact present in the situation and what past elements could have been learned, as well as by physical, including artifactual, possibilities. Similarly, all ecological mechanisms assume the presence of some given level and kind of motivational orientation on the part of the actors involved. Thus the main theoretical issue is not which mechanism is present in some absolute sense but, rather, at what point in the analysis it is pragmatically appropriate to explicate which type of mechanism while making what assumptions about the other type.

This issue has often been obscured, perhaps partly because of a lack of synthetic effort, but surely because of the intellectual legacy of functionalism. For in its classical statement functionalism draws attention away from the question of causal mechanisms simply by assuming that social structures operate in such a way as to maintain themselves in some stable state (Merton [1949] 1957, pp. 19-84; Radcliffe-Brown 1952). Such an assumption permits one to make the type of ecological argument characteristic of "structural-functional requisite analysis": that the existence of such a state implies that certain activities contributing to its maintenance are perforce somehow being performed (Levy 1952, pp. 149-197). But such an argument invites questions about the status of psychological mechanisms in the situation (Brown 1963, pp. 109-132; Homans 1964; Inkeles 1959). Classical functionalism avoided such questions by assuming, in effect, a complete congruence of psychological mechanisms with ecological explanatory devices, thereby giving a teleological cast to social structure (Malinowski 1944) and inviting tautologous formulations. It is possible to drop this assumption and still maintain a nominally functionalist position. But the questions begged as a result of so doing transcend the original functionalist position to such a degree as to suggest the adoption of a different perspective al-

together. The focus becomes one of discovering the nature of causal mechanisms that interconnect different aspects of social structure, rather than one of assuming the mechanisms and thereby inferring structures (Dore 1961).

This position suggests a resolution, in principle, of another question in regard to causal mechanisms that has often plagued the analysis of social structure: the "statics versus dynamics" problem. Masking the theoretical issues is the immediate terminological question of whether the concept "social structure" should be restricted in its reference only to those elements of the social order which remain constant over time. Thus Firth (1951), for example, proposes to use the term "social organization" to denote patterns of change, in contrast with "social structure," which indicates patterns of stable elements. Analogous to this distinction is the familiar "process versus structure" dichotomy. But processes are inseparable from structure, in the sense that any social structure is held together by mechanisms relating its elements (see Vogt 1960; see also Gurwitsch [1950] 1957-1963, vol. 2, pp. 403-446). Operation of such mechanisms through time results in more or less change or stability in the values of the variables reflecting the social structure. Consequently it is misleading to treat patterns of stable interrelations as if they were basically different from patterns of change, inasmuch as both types of pattern result from the operation of social forces through causal mechanisms. It is not the case that change, simply because it is change, somehow involves "more mechanisms" than does stability.

### Toward an eclectic view

The current path of what one might term "post-functional revisionism" thus suggests that dynamic strain is always present on some levels of social structure (Moore 1963), and, while hardly Marxist in its orientation, suggests the fruitfulness of a reconsideration of some of the basic insights of Marx in this context. The five structural aspects which we have distinguished are interrelated by a complex of dialectical tensions which, in principle, can be concretely operationalized and explicated as a set of interrelated psychological and ecological causal chains cutting across the five aspects of social structure, with their operation resulting in more or less "stability" and "change."

The immediate problem would seem to be, first, the allocation of proportional contributions of variance among the cultural, systemic, morphological, group, and individual aspects of social structure. One can then seek to explain the statistical results

thus obtained by assuming various psychological and ecological causal mechanisms whose existence can subsequently be verified or disproved by detailed analysis of actual social situations.

An as yet small, but perhaps significant, literature is beginning to arise utilizing essentially this perspective and centering—at least in its initial stages—on the analysis of “structural” or “compositional” effects. Thus far it has proved possible, in such analyses, to isolate individual from group effects and to separate both individual and group effects from a residue involving morphological, systemic, and cultural properties (Blau 1960; Lazarsfeld & Menzel 1961; Davis et al. 1961). Some inferences of precise mechanisms have been made, mostly centering on socialization on the individual level; interpersonal strategies yielding “social approval” on the group level; and emergent consolidation of normative systems through adaptation between the group and systemic, and group and morphological, levels (Davis 1963; also see Heider 1958; Blau 1964).

It is as yet too early to assess the probable ultimate fruitfulness of this approach. Various problems seem to arise, for example, in developing consistent operational ways of moving from the group to the systemic, morphological, and cultural levels of analysis. The main difficulty seems to lie in systematically relating interpersonal phenomena to ecological processes (in the traditional sense), value systems, and various (often vaguely conceived) macrostructural, dialectical “forces” (Boudon 1963; Selvin & Hagstrom 1963; Tannenbaum & Bachman 1964). However, with increasing recognition that many theoretical controversies regarding social structure either reduce to the use of different words to denote the same things or arise from an emphasis on different relatable aspects of the same phenomena, will perhaps come a fruitful synthesis, eventually more original than eclectic.

## SOCIAL WORK

The objectives of social work are to help individuals, families, communities, and groups of persons who are socially disadvantaged and to contribute to the creation of conditions that will enhance social functioning and prevent breakdown. These objectives commit the social work profession both to helping persons adapt socially in keeping with their capacities and the norms and values of the society, and to modifying or reforming features of the social system. The term "social worker" refers to a special group among those employed in rendering social welfare services or conducting programs of agencies and institutions that make up the social welfare system. The professional social worker is expected, because of his specialized training and experience, to bring a high degree of skill to the process of helping, and modifying the social conditions of, individuals, groups of persons, and communities. The special competence of the professional social worker is exercised in such tasks as providing material assistance for the needy and dependent; assisting those of whatever means who have difficulties in adjusting to their economic and social environment because of poverty, illness, deprivation, conflict, or personal, family, or social disorganization; and participating in the formulation of social welfare policies and preventive programs.

### Emergence of the social work profession

As a deliberate concern for helping the indigent and less privileged members of society, the roots of social work go back to religious and humanitarian impulses evident in the histories of most civilizations. As a formal organization of efforts by specialized personnel to help such persons, social work is an accompaniment of nineteenth- and twentieth-century industrialization, with its associated problems of social dislocation from a more stabilized family and community system. The aspirations of positivist social science and the counterviewpoints to social Darwinism in the late nineteenth century contributed to the conviction that rational and scientific solutions to social problems could be found through social reform and individual guidance. The trend has been from personal and religious charity, to organized philanthropy, to public acceptance of

responsibility for programs of professional services. [See SOCIAL DARWINISM.]

As a profession, social work emerged during the twentieth century, when it became an acknowledged, full-time occupation, with established training schools, professional associations, and a high degree of self-consciousness about its status. Professionalization developed first in the United States and western Europe. Before 1910 independent schools for training social workers were founded first in the Netherlands and then in the United States, Great Britain, and Germany. Between World War I and World War II social work schools were widely established in Latin America and countries of the British Commonwealth. Since World War II, professional schools have opened in Asia, the Middle East, eastern Europe, and more recently in Africa. By 1950 a United Nations survey enumerated 373 schools of social work in 46 countries representing three-fifths of the 77 member nations. Since 1950 new schools have been founded in all regions, but especially in the new nations of Africa (United Nations 1950; 1965). Both national and international associations of social workers have been formed, professional journals and other publications issued, codes of ethical conduct promulgated, and official or legal recognition achieved to distinguish the professional social worker from other social welfare personnel.

Programs of social services under private and public auspices have expanded, and the number of social welfare workers has increased. The number of professionally trained social workers has also grown, but they still constitute a minority of all those engaged in social welfare work. In the United States in 1960, approximately one-fifth of the 105,000 social welfare workers had sufficient education to qualify as professional by the profession's own standards (*Salaries* . . . 1961). The proportion of professional to nonprofessional social welfare workers appears to be smaller in other countries. The profession thus faces a persistent problem of trying to establish and maintain an independent identity.

With the growth of educational facilities, the term "social worker" has increasingly come to refer to those specifically trained for social work, but the designation does not uniformly connote professional status in various countries. It sometimes refers to any sustained individual charitable efforts, and it usually includes employees, whether specifically trained or not, of public and private organizations serving the indigent or persons with problems of health, handicap, or deficiencies that may affect their social adequacy ("The Term . . .

1961). There is evidence that professionalization of social work is proceeding in similar form and with similar problems in various parts of the world. This is, in part, a result of the pressing demand for trained personnel and the diffusion of patterns from the more developed countries. Leaders in social work in developing nations often have had some of their training in western Europe, Canada, or the United States (*Interprofessional* . . . 1963), or have participated in international conferences in which professionalization has been prominently discussed.

Because most social workers are salaried employees who are characteristically dependent on bureaucratic organizations (generically called agencies), the development of a professional identity apart from the organization where they are employed has presented another persistent problem. The balance of influence over training schools has shifted gradually from agency to professional control. Moreover, there is a gradual tendency for professional associations to represent collective interests transcending those of social workers in particular agencies or fields of practice. Professional identification is also encouraged by frequent meetings and conferences of social workers on local, regional, national, and international levels.

### Demography of the social work profession

A number of characteristics of the personnel of social work bear on the nature of the profession. Women predominate, although the proportion of men has been increasing. In the United States in 1960, 60 per cent of all social welfare workers, but 68 per cent of the members of the professional association, were women. The proportion of female welfare workers in the United States decreased by nearly 10 per cent between 1950 and 1960, and the more balanced sex ratio of students in professional schools probably reflects the trend toward equality of the sexes in American society as a whole. In other countries, the preponderance of women is probably even greater, despite the efforts of professional and governmental bodies to recruit men into welfare work. Men tend to gravitate to supervisory and executive positions, but women nevertheless hold a considerable proportion of these jobs. This introduces sex-role conflicts within social work and between social work and other professions. As a "female profession," social work shares the generally lower prestige of women in the occupational world; and this, in turn, contributes to the difficulty of raising salaries in comparison with professions dominated by men. Career patterns and job mobility also tend to be differen-

dated by sex. Thus, a changing sex ratio may be expected to have a significant effect on the profession.

Although information on the social class of origin of social workers is limited, the profession appears to serve as a channel of upward mobility for both men and women (Pins 1963, chapter 3). Compared with other professions, social work has been relatively accessible to persons from minority groups and lower-class backgrounds. Social workers with professional schooling probably come from class positions that are higher than those of persons entering social work without special training but not as high as the level of persons entering professions such as medicine or law. Unlike these professions, social work clearly does not have the advantage of gaining prestige from the class background of its members. Rather, entrance into the profession often raises the class position of its members, and this probably affects both internal and interprofessional relations.

**Patterns of distribution and training.** The character of the profession is affected by the location of professionals within the social welfare system. Programs of income maintenance, such as support for dependent children and the aged and ancillary services to social insurance beneficiaries, employ the largest share of all welfare workers but the smallest proportion of those professionally trained. In the United States approximately one-third of all social welfare workers, but only 5 per cent of professionally educated social workers, were employed in public assistance programs in 1960 (*Salaries . . . 1961*). On the other hand, medical and psychiatric social work programs together employed 9 per cent of all social welfare workers but 29 per cent of those professionally trained. Professional social workers are also disproportionately to be found in noninstitutional child welfare programs. The consequence of such a differential distribution is to focus professional attention on a narrower range than that embraced by the social welfare system and to provide an unbalanced degree of professionalization among the various welfare programs. Only 3 per cent of public assistance workers in the United States in 1960 were professionally trained, whereas over half of the workers in medical and psychiatric programs were trained. This imbalance tends to promote viewpoints in the profession that define certain places of employment as more "professional" and others as less so. Such viewpoints underlie attitudes about suitable locations for professional practice. Similar tendencies have been noted in other countries.

The relative concentration of professionally

trained social workers in private, as distinguished from governmental, agencies has also affected the conception of attractive locations for professional employment. Approximately two-thirds of all social welfare workers in the United States in 1960 were employed by federal, state, or local governments, whereas only about half of the professional social workers were so employed. In other countries, where the private sector tends to be smaller—and usually church-supported—the attraction of private agencies does not appear to have been so great, although the absence of a large private sector is sometimes cited as a limitation on professionalization.

The disproportionate location of professional social workers in private agencies and in psychiatric, medical, and child welfare fields in the United States has historical explanations. The social workers most concerned about professional identity in the early decades of the century were those associated with fields in which clinical professions having greater prestige practiced, especially medicine and psychiatry. During the 1920s these social workers found psychoanalytic theories congenial as a basis for developing a distinctive mode of practice and supporting a claim to higher status among helping professions (Lubove 1965); the schools of social work largely accepted this viewpoint. When large-scale public assistance programs were developed as part of the social security system during the depression of the 1930s, they were primarily conceived as income maintenance programs to be administered by government employees rather than as programs requiring professional services. The charitably sponsored private agencies, now relieved of their traditional responsibility for economic aid, became especially receptive to the clinical orientation of trained workers who were also attracted to the clinical services associated with public programs in health, mental hygiene, and child welfare. The location of professional workers within the social welfare system has, in turn, affected recruitment and training, encouraging further emphasis on the clinical practices within social work. Nevertheless, professional social workers have often occupied supervisory and administrative positions in public welfare, and the profession has sought to influence public welfare policies through its associations and spokesmen.

The training and distribution of professional social workers in the United States are being further shaped by new demands on social work in the 1960s. The 1962 amendments to the Social Security Act explicitly emphasized social services to recipients as an objective of public welfare, giving

impetus to the upgrading of educational requirements for welfare workers. New programs involving broadly conceived community approaches to delinquency, poverty, mental health, and other social problems have encouraged recognition of functions for social workers other than direct services to clients; and the increasing integration of private agencies into such government-supported programs has reduced the distinction between private and public auspices. A greater proportion of students at social work schools has been attracted to group work and community organization. The literature on professional practice has reflected greater interest in the social sciences. Moreover, the problem of professional manpower has received increasing attention from the profession's leaders and government officials. In other countries, where the undersupply is even more acute and trained social workers have gravitated toward clinical locations, some comparable trends are evident. Especially in less developed countries, the practice of community development—proposing a comprehensive attempt to affect the complex of institutions of a total rural or urban community—has attracted professional social workers and has been emphasized in their training. [See COMMUNITY, *article on* COMMUNITY DEVELOPMENT.]

The shortage of trained social workers is the manpower condition that underlies the patterns of distribution in developed as well as underdeveloped countries (Conference . . . 1965). It has given rise to active recruitment programs in most countries; and it has stimulated attempts to distinguish levels among professional responsibilities requiring varying amounts of training, as in Great Britain (Great Britain . . . 1959). In the United States the shortage has generated interest in the education of subprofessionals and in various patterns for their use in social agencies along with more highly trained workers, thus requiring new conceptions of the practice roles of professional social workers. There has been wide recognition that social workers cannot be trained in large enough numbers under present conceptions of professional education to fill all social welfare positions, even when many positions are excluded as not requiring professional training. The manpower shortage also complicates the efforts of the profession to maintain or raise its entrance standards. Such standards are under pressure to broaden the definition of professional membership, acknowledge the alternatives to professional training for entrance to the profession, and adapt to such demands or face submergence within the large mass of non-

professional workers. The response of the profession to these pressures will determine the character of recruitment, training, and utilization of professional social workers (National . . . 1966).

### Professional training

Who is a professional social worker and how one enters the profession are variously, and sometimes ambiguously, defined by different countries. Personal commitment and activity in professional affairs may serve to distinguish "professional" from other social welfare employees in some countries. Elsewhere (France, for instance), a state license designates the professional social worker. In general, however, formal professional education is increasingly the primary channel of entrance.

**Schools of social work.** Schools of social work throughout the world may be roughly compared on the basis of their number and distribution, their sponsorship and location within the educational system, and the diversity of their financial support. Western Europe and North America have a great number of both private and public schools of social work; private schools typically receive subsidies from public funds through various governmental budgets. The location of social work training varies: in Great Britain it is usually part of the curriculum of social studies departments in universities and colleges; on the Continent there are separate technical institutes; and in the United States and Canada there are postgraduate divisions for social work education. In Latin America, Asia, the Middle East, and Africa schools of social work, though still few in number, have increased markedly since 1950; and private or church-sponsored schools are becoming integrated with those established within public educational systems. The Soviet Union is reported not to have specialized schools or an established profession of social work (Madison 1962), although correctional workers are specially trained educators.

The relationships between professional schools and their sources of support may affect the type and character of training. Standards are set by law or government in a few countries, such as France and Brazil. In the United States, the agencies of government that furnish subsidies for many students and some faculty salaries are usually interested in obtaining personnel for the established programs they administer and, hence, tend to favor training for direct, clinical services. In countries where there are associations of schools of social work, these generally seek a large voice in the determination of their own standards.

Schools may find it feasible to expand their capacities in those fields of practice already most professionalized, thus giving less emphasis to newer fields and broader social approaches. The problem of achieving balance has been recognized by both educators and governmental officials (Blackey 1964; Wittman 1965).

Completion of secondary schooling is generally the minimum requirement for admission to social work schools. In the United States and Canada, and in some schools of several other countries, the student must hold a baccalaureate degree in order to be admitted. Age limits, both lower and upper, are sometimes specified. Restriction to female students was at one time common, particularly in Latin American schools, but sex limitations are disappearing. Professed humanitarian values and commitment to service are personal qualities usually sought in applicants, and previous academic performance is always taken into account.

Throughout the world, most schools have relatively small enrollments, usually under one hundred. However, schools are expanding. In the United States in 1964 the largest school reported 409 full-time students, and 38 of the 59 schools reported full-time enrollments of one hundred or more, constituting approximately three-fifths of the 7,366 full-time students in all schools (*Statistics . . . 1964*, table 4). Social work schools also provide instruction, sometimes in separate courses, for many part-time students, only some of whom are enrolled for the professional degree; precise data are available only for the United States and Canada, where part-time students constituted approximately one-quarter of all students enrolled in the professional curriculum in 1964 (*Statistics . . . 1964*, table 2).

Students at most schools fall into two groups: those entering as an immediate continuation of their schooling and those entering after some period of employment in social welfare. In the United States the latter are a decreasing proportion, but increased public funds for training employed personnel may retard this decrease. Such students are generally older; thus their proportion in American schools may be estimated from the fact that in 1964 students 31 years of age or older constituted 30 per cent of all full-time students working for the professional degree (*Statistics . . . 1964*, table 9). Prior work experience is accorded decreasing importance relative to recency of academic study, but the accommodation of students with different backgrounds presents a characteristic problem in curriculum planning. The content of academic prereq-

uisites tends to be general—usually specifying only that courses in a number of social sciences be presented—and the academic backgrounds of students vary widely.

**Characteristics of training.** Social work education includes both theoretical and practical training. Practical training may be provided (as in Great Britain and countries it has influenced) by full-time field placements of students intermittent with classroom lectures or after completion of theoretical courses; or it may be provided concurrently with classroom work (as in the United States and countries influenced by it). Laboratory agencies for practical training under control of the professional schools are provided for a small proportion of students, but most are trained in selected, available agencies in the community. Practical field work generally requires "supervision"—that is, instructional direction by a trained social worker in an agency setting. A continuing difficulty in accommodating larger enrollments is the finding of suitable "field placements" for additional students. This system sometimes limits the range of agencies within which training may be given, particularly in new fields of practice, where few professionally trained social workers are employed.

The content of social work training tends to be organized around methods of social work practice, and field instruction is usually identified with one (but sometimes several) of the methods. The more theoretical portions of the curriculum provide knowledge of human behavior and social life deemed useful for competent practice. Courses on social welfare policies and the structure of welfare services of the country are usually required, and often some courses in social work research. Most students are trained in the casework method; in the United States in 1964 three-fourths of the full-time students were so identified. Casework method stresses interpersonal skills (usually the casework interview) to help individual clients or families solve problems of personal or social stress. The development of casework method has drawn heavily on psychoanalytic theory and dynamic psychology; and their perspectives pervade this training, although there is a marked trend toward the inclusion of a wider range of knowledge from the behavioral sciences. Training in a second method, called social group work, seeks to develop skills in using interaction processes of specially constituted or selected groups to help clients. A third method, called community organization, involves training to work with groups and organizations within the community in the solution of social problems.

Finally, a few students are given special training in social welfare administration or in social work research. Schools in developing countries have emphasized training in community development to a greater extent than have those in Europe and North America. However, community organization is currently being conceived more broadly in the United States, and it represents the most rapidly expanding part of the curriculum.

Along with more academic and technical training, social work schools usually give deliberate attention to the socialization of the student into the profession. The professional practitioner is presented as a model in most classes, but especially in field placements. Faculty advice and supervision by field work instructors tend to be close and fairly continuous through the years of study, and frequent evaluations of progress in acquiring professional norms, values, and orientations are often shared with the student. Strong professional identifications seem to lead students to prefer subsequent employment in positions where other professional social workers are practicing. Some observers of social work education in the United States have expressed concern with the academic level of graduate study and the focus of training on therapeutic rather than preventive content (Kadushin 1965). However, there is evidence that the social work curriculum is changing in terms of greater emphasis on social science materials and broader conceptions of the roles for which social workers are to be trained.

The number of years required for completion of social work training is related in part to the educational level attained by the students prior to enrollment in professional schools. If students are admitted directly from secondary schools, the length of study is usually three or four years. This generally corresponds in duration to the training given other technical professionals, such as teachers and nurses. The most significant exception to this widespread pattern is found in the United States and Canada, where the length of training is two years, but completion of four years of college is a prerequisite for admission.

Faculty members for social work schools are recruited primarily from practitioners in social agencies. Academic work beyond the professional degree has not generally been considered necessary. In recent years, as social work schools have become more integrated with universities, faculty members with advanced degrees have been sought; in the United States, professionals with doctorates in social work or in a social science are increasingly

employed. Fifteen schools of social work offered doctorates for advanced study of social work in 1964. Faculty members with graduate degrees in other academic disciplines—especially sociology and psychology—are often used, as are part-time instructors from other professional schools, especially from psychiatry, medicine, and law. While staffing patterns differ among countries, and a pattern of collaboration between practitioners and social scientists is fairly general, the point of view of the professional is usually dominant. There is widespread recognition of an acute shortage of personnel suitable for faculty membership.

### Professional practice

As previously noted, the profession of social work is almost exclusively practiced within agencies. Private practice, particularly of casework, has grown in the United States (Levenstein 1964), but it is not common. Social agencies range from those in which social workers constitute the exclusive or predominant professional personnel—such as family and children's service agencies, some community centers, and some social welfare planning councils—to institutions in which social workers occupy positions complementary or secondary to other professionals—such as hospitals, clinics, and public schools. Interaction between organizational and professional interests constitutes the continuing context for social work practice (Vinter 1959; Billingsley 1964).

The type of client and the kind of service offered are initially fixed by the purpose of the agency. A characteristic part of social work practice is "intake"—that is, determination of whether the client and the problem he presents can be properly accepted or should be referred to a different agency and, then, whether the client can be helped by the available professional treatment. In those instances in which clients are residents of correctional or medical institutions, pupils of schools, or cases before the courts, selection is further limited. The agency may also, by organizational decision as well as by the selective employment of social workers, determine the method of practice to be utilized. The introduction of different methods may be as much a decision of agency boards and executives as of professional practitioners. Although the executives are often social workers, practitioners are subject to evaluation in terms of agency criteria, such as productivity and conformity to routines, and these may not always be consonant with professional criteria of optimum service to clients.

There is always at least latent strain between

the requirements of professional autonomy and the constraints of the organization. Such strain is less evident where professional social workers occupy all levels in an agency. Where they are in a minority or subject to authority of other professions, the differentiation of a distinctive function for the professional social worker may become blurred, and its determination may become a matter of concern. Where untrained workers constitute a large proportion—as in most public welfare agencies—professional social workers often occupy supervisory or administrative positions. In agencies that provide mental health services—such as child guidance clinics, clinical and outpatient services of mental hospitals, and some community health agencies—social caseworkers (and sometimes social group workers) are often parts of clinical teams consisting of psychiatrist, clinical psychologist, and social worker. Problems of establishing appropriate roles and working out interprofessional relations have been observed, particularly those centering on the higher status often accorded to, or assumed by, the psychiatrist (Michigan . . . 1957).

The institution of "supervision" is characteristic of the organization of much social work practice. More experienced or more highly trained practitioners serve as "supervisors," not only in the administrative sense but as colleagues with whom practitioners are expected to discuss specific cases and problems of practice. This is viewed as a continuation of professional education for the social worker (usually on an individual, tutorial basis) and as a safeguard for standards of practice. Even trained social workers are supervised. This has been said to retard the achievement of professional independence, and it has recently come in for criticism and experimental modification (Burns 1965). No detailed empirical study of supervision in its organizational and professional context has yet been published, although it appears to be a common pattern for the organization of practice in most countries, it is often associated with the use of consultation about particular cases with other professionals, such as psychiatrists or other physicians, psychologists, and lawyers.

Social workers tend to identify themselves along lines of practice methods as caseworkers, group workers, or community organization workers, and their agencies are often similarly identified. There is experimentation, in both training and practice, with multiple uses of these methods and with their modification in order to find the most appropriate patterns of service. Particularly noteworthy are ef-

forts to devise new approaches to interpersonal helping processes, to the structuring of service and treatment organizations, and to the utilization of social action and other methods of community work. In the more clinical practices, such professional developments are strongest in the United States and western Europe, but new techniques in community organization are appearing most rapidly in other countries, where community development work in rural and urban areas is prominent.

**Professional-client relationships.** The major part of social work practice takes the form of face-to-face interviews with individuals, families, or groups of clients at the agency. Compared with other helping professions, however, social work conceives its practice as involving more contact with clients in their homes and elsewhere in the community. For example, work "in the streets" with gangs of delinquents is carried on by a number of agencies, and extensive work with neighborhood groups, settlement houses, and voluntary associations in the community is characteristic of some community organization practice. In addition, community organization practiced in welfare planning or fund-raising agencies calls for other relationships. The clientele of social workers thus consists of a wide range of persons, groups, and community organizations. Clients of public agencies are usually from lower socioeconomic levels as compared with the clients of private agencies (Cloward 1963). The latter may charge fees to clients who can afford them, but the services of social workers are usually provided without cost to the clients. Among the helping professions, social work also tends to adopt a more comprehensive conception of the social context of the client's problem. Hence, professional service often entails contacts with family members, employers, associates, and agencies that affect the client. Even so, critics both outside and within the profession frequently urge a wider social perspective, and such criticism is partly responsible for recent programs dealing with problems of delinquency, dependency, and illness in terms of the social environment.

The relationship between the professional social worker and his client is governed by strong norms of confidentiality and responsibility; it is seen as a privileged relationship delimited in function and content, calling for objective, emotionally neutral interest and impartiality in the rendering of service (Wilensky & Lebeaux 1958, pp. 298-303). Such norms are more explicitly recognized where professionalization is most advanced, but they are widely asserted in international literature as proper

for the professional social worker. Recognition of the professional nature of social workers by their clients is not always equally evident. This appears to encourage self-consciousness as well as concern for opinions of the staff and financial supporters who seem seriously concerned about their practice and image. The social worker views his practice as the use of his professional self to establish and maintain a helping relationship with his client, whether individual, family or community group. The centrality of the relationship is a basic value, as an indication that help is being given and thereby the worker's effectiveness is enhanced with the help they receive. However, in the United States less than half of the reports of private community agencies contain a second interview or contact with the client after discharge can be found in their case records, with the caring of being given over to the client.

Evaluation of social work. Importance of social work practice has long been recognized by the profession as a counterpart of its claim to professional competence. However, numerous evaluations of the effectiveness of social work have found problems ranging from those of policy, funding, and theoretical orientation. However, in all cases, many of the specific difficulties of the social work were never taken account of, except for the limited application to the evaluation of the social work itself, for example, in the evaluation of the effectiveness of the social work practice.

[illegible]

These findings are consistent with the hypothesis that the use of the word "and" in the sentence "John and Mary are married" is a marker of a specific type of relationship, namely, a relationship of equality. This is consistent with the findings of other studies which have shown that the use of the word "and" is a marker of a specific type of relationship, namely, a relationship of equality.

Marley & colleagues (1999) conducted a meta-analysis examining the impact of placement of children in foster care. All research had greater evidence for placement of children in foster care than in institutions or in orphanages. Marley & colleagues (2000) conducted a meta-analysis of 23 studies that examined the impact of placement of children in foster care. They found that placement of children in foster care had a positive impact on children's cognitive, emotional, and social development. They also found that placement of children in foster care had a positive impact on children's physical health. They concluded that placement of children in foster care is a positive intervention for children who are in need of a family.

strate only modest effectiveness of the theoretically oriented approaches utilized. Such findings encourage social workers to examine the theoretical bases for their methods and have contributed to a growing emphasis on manipulation of the social and community context in which the problems of clients arise.

Evaluation of the impact of community action programs presents complex problems that have only recently received systematic attention (see Freeman & Sherwood 1965). An attempt to affect delinquency rates by the use of street gang workers has been evaluated by Miller (1962), who found that such workers had little effect on delinquency rates. Others have evaluated the impact of community action (e.g. Ohlin 1960) or of community organization to enhance the position of the poor (e.g. Hagerstrom 1964); generate programs of such complexity that their rigorous evaluation is unlikely to be achieved until the modes of intervention are made more explicit and the results more clearly defined. The need for a more systematic approach to the evaluation of community action programs is thus apparent. The following review of the literature on the evaluation of community action programs is intended to provide a basis for the development of a more systematic approach to the evaluation of such programs.

career patterns. Another common factor in the career pattern of women is the fact that many women leave the profession after having interrupted their working life when they accompany their husbands to new jobs or when they become mothers. This is also one of the most characteristic differences between men and women social workers. There are also differences between men and women professional social workers that are partly a function of the disproportionate number of men in higher posts and in fields of practice, such as community organization work, which are higher (see Haker 1963 p. 537).

[illegible]

over involvement in public assistance agencies, causing disadvantaged parents, especially parents of inner-city youth.

### Professional associations

Many organizations to which social workers belong are termed the house of professional family or some similar phrase of interest, such as public and child welfare, law, medicine or mental health. Two types of strictly professional associations have emerged: the type that serves individual social workers as a membership association concerned with professional development in the profession, standards of professional practice, standards of educational preparation, ethics, and the status of social work toward the profession. The other type is the association of advocates of social work interests with policy and lobbying, educational requirements and standards, support for professional equity, and acceptance of formal status benefits. The former and members of these two types of associations assume, and then often share, the responsibility for professional equity, whereas the latter would regard it as their responsibility to represent themselves as the professional community or social workers as the community in practice, and affairs of discipline, equity, development and the status of social work. The distinction more recently, especially at schools, has been in that either be an *association* (United Nations, 1980). In Europe, where professional membership associations are rare and well-regulated, the association of schools play greater but still significant role in the United States with regard to discipline, equity, and status, but not membership. In Europe, where professional membership associations are rare and well-regulated, the association of schools play greater but still significant role in the United States with regard to discipline, equity, and status, but not membership.

Various international social welfare professional associations have formed since the turn of the century, but none is a majority of countries. However, organizations have proliferated, specializing first in the number of professions social workers, second in their geographic scope, and third, their social philosophies have culminated, enough to constitute but single national organizations. The National Association of Social Workers (NASW), which was organized in 1955, presently represents 100,000 members nationwide. For all social workers in the United States, with exception that recognized as one member, NASW remains a national-level association of social work professionals. In the United Kingdom, the Council on Social Work Education (CSWE) established in 1962, is

only for accreditation only those schools which grant the master's degree after two years of graduate study. It also maintains a division for undergraduate departments that give social work instruction regarded as "preprofessional."

The International Federation of Social Workers, founded in 1932 and reactivated in 1950 after the interruption of World War II, is composed of national associations of social workers. The International Association of Schools of Social Work has also been established. These organizations carry on informational and educational activities, meeting biennially along with the International Conference of Social Work, an organization with broad social welfare interests.

Membership in NASW accords recognition of professional status in the United States and Canada. A degree from an accredited graduate school is an eligibility requirement for certain civil service positions of state and federal governments. NASW has sponsored legal certification restricting the use of the title "social worker" to those having specialized certifications, and in 1980 four states had laws protecting the title. In France and Puerto Rico, social workers are licensed, and several countries have established legal requirements for schools of social work. In 1960, NASW founded the Academy of Certified Social Workers (ACSW) to designate social workers who are members of NASW and have two years of successful social work experience under the supervision of a member of the academy. The effect of ACSW will be, after a transition period, to establish a differential within the profession that is based on practice experience versus their education. Proposals to broaden the base of the profession by admitting social workers with college degrees and a certain number of years of experience to some form of membership in NASW were unsuccessful up to 1980. In the continuing debate over the issue, some members argue that present membership restrictions may generate competitive professional organizations with other qualifications for membership. It is more support the position of a "professional" rather than an "occupational" association. The issue may be expected to persist, especially in the face of the shortage of trained social workers and the influence of parents with qualifications other than social work training, who compete in social welfare under large public programs in such areas as mental health, poverty, delinquency, and community youth.

Associations of professional social workers in a number of countries have adopted or proposed

codes of ethics, and in the United States NASW promulgated such a code in 1960. It pledges members to a series of obligations, including primary responsibility to the client, confidentiality, recognition of the limits of professional knowledge and competence, appropriate respect for colleagues, priority of professional over personal interests, and other standards of professional conduct. There has also been discussion of an international code of ethics by the International Federation of Social Workers.

### Future directions

The character of the profession is being affected by several lines of development within social work. One of these is the increased emphasis on institutional and community change, in which the client is encouraged to participate. A number of governmental programs have adopted this approach, making the environment rather than the individual the major target of intervention. Social workers involved in these programs are turning to broader theories of social science in their training and practice and are enlarging the scope of community organization.

Social workers who help the client to function better in his individual situation are also experimenting with additional techniques. There is renewed consideration of the whole family, and treatment methods more commonly include the use of group approaches. Moreover, social workers are increasingly turning to behavioral psychology as a guide for practice rather than to the psychoanalytic doctrines upon which the therapeutic methods of social work have largely depended.

Manpower pressures are stimulating experimentation with new forms of practice and with the differentiation of tasks for which varied training is required. The increasing responsibility of social workers in the implementation of large public programs and greater security about their competence are encouraging both basic and evaluative research. Finally, achievement of more secure status and recognition is increasing the social work profession's ability to define the role it will play in the changing society.

### BIBLIOGRAPHY

The absence of extensive empirical studies limits analysis of the social work profession. Useful descriptive materials on social work education and other aspects of the

profession can be found in the four United Nations surveys published under the title *Training for Social Work* in 1950, 1955, 1958, and 1965. Current developments in various countries are reported in *International Social Work*, published bimonthly by the International Conference of Social Work. See Great Britain . . . 1959 for an extensive study of social work in Great Britain, focusing on manpower and training; Timms 1964 provides a history of British social work in mental health; and Rodgers & Dixon 1960 presents an intensive study of social workers in a British community. For the United States, the *Encyclopedia of Social Work* contains a wide range of information; it was published in 1965 by the National Association of Social Workers, replacing an earlier series, the *Social Work Yearbook. Salaries and Working Conditions* . . . 1961 includes some data on trends in the United States since 1950. The emergence of the profession in the United States is analyzed historically in Lubove 1965. The most complete sociological analysis of the profession is a perceptive study of social welfare, Wilensky & Lebeaux 1958; other general analyses of the profession include Pollack 1952; Greenwood 1957; Cohen 1958; Meyer 1959. For studies of the characteristics of social work students, see Pins 1963 and Berengarten 1964. Manpower issues are reviewed in National . . . 1966. The Council on Social Work Education's publications include the *Journal of Education for Social Work*, regular informational bulletins, and an annual series entitled *Statistics on Social Work Education*. The National Association of Social Workers also has a publications program that includes two quarterly journals, *Social Work and Abstracts for Social Workers*, as well as regular bulletins on personnel information and professional developments. Professional journals, especially *Social Service Review*, *Social Casework*, and *Child Welfare*, frequently include discussions of problems of professionalization. Developments in public welfare bearing on the profession may be found in the journal *Public Welfare* and in other publications of the American Public Welfare Association, as well as in occasional publications of the Welfare Administration, U.S. Department of Health, Education and Welfare. In addition, more technical papers about social work knowledge and practice often supply insights into trends in the profession.

## SOCIALISM

The word begins in obscurity. Though various origins have been suggested, the first use in French has commonly been ascribed to the *Globe* of February 13, 1832, where the word *socialistes* was chosen to describe the followers of Saint-Simon. (However, a recondite reference to socialism a year earlier, in the religious journal *Le semeur*, has been uncovered.) Englishmen have claimed the honor of its coinage, since the word "socialist" did appear in the *London Co-operative Magazine* in 1826, although it was not until several years later that followers of Robert Owen began describing themselves as socialists. Clearly, however, the term was in the air, for it described a converging mood; and the first article on "socialism" as an idea in opposition to "individualism" was written by Pierre Leroux and appeared in 1835 in the *Encyclopédie nouvelle*, edited by Leroux and Reynaud. The word recurred thereafter in various writings by Leroux.

By 1840 the term "socialism" was commonly used throughout Europe to connote the doctrine that the ownership and control of the means of production—capital, land, or property—should be held by the community as a whole and administered in the interests of all. Within 120 years after the term became known in Europe, the doctrine had spread so widely that one could find regimes in Sweden, Great Britain, the Soviet Union, China, eastern Europe, Cuba, Algeria, Egypt, Syria, Israel, Guinea, Kenya, Tanzania, India, Burma, and Ceylon calling themselves socialist, and the labels

Arab socialism, African socialism, and Asian socialism used to describe the grafting of indigenous traditions onto ideological doctrine. Rarely in the history of the world has an idea taken hold so deeply and dispersed so quickly. One would have to go back to the spread of Islam, in the century and a half following the death of Muhammad, to find a comparable phenomenon. And the analogy is not without relevance, for one finds in both instances the promise of a perfect community, the effort to create a solidarity larger than that of tribe or class, a reaction to the meaninglessness of existing religious beliefs, a militant proselytizing spirit, and leadership by new elites. In fact, the comparison with Islam is meant to suggest that the spread of socialism cannot be wholly accounted for in economic or class terms. The socialist movement has (or had) the character of a secular religion, and only from this view can one explain its development and internal vicissitudes.

This article will discuss the formulation of early socialist doctrine, the differentiation of the socialist movement and the spread of socialism, the role of socialist parties, and varieties of socialist belief since Marx. [*Marxist views and positions are elaborated in MARXISM and in the articles under COMMUNISM.*]

### Growth of the doctrine

**Beginnings.** The meaning of socialism, both logically and sociologically, can only be understood as a contrast to individualism. The Enlightenment, English political economy, the French Revolution, and the nascent industrialism had all combined to produce what in 1826 a disciple of Saint-Simon called individualism. In this doctrine, society existed to serve the individual and the pursuit of his own satisfactions; natural rights inhered in each individual, and government was not to regulate the economic life of society. Even the French Revolution, with all its passion for virtue and its defense of popular sovereignty, fostered the idea of economic individualism.

The attack on individualism drew its strength from a Catholic and a socialist point of view. Bonald and de Maistre, both theocrats, were militantly against "political Protestantism" and asserted that man exists only for society. Particularly after the revolution of 1830, many French writers of a conservative bent—Lamartine, Balzac, Sainte-Beuve, Lammenais, and Tocqueville—expressed their alarm about *l'odieux individualisme* and held it responsible for the disintegration that they felt was occurring in their society.

While the conservatives attacked the political

philosophy which they linked to the French Revolution, the socialists were appalled by the economic doctrine of laissez-faire: this, Louis Blanc declared, was responsible for man's ruthless exploitation of man in modern industry. Under industrialization, the socialists alleged, the individual had been torn from old moorings and had no anchorage. Friedrich Engels, writing about London in *The Condition of the Working Class in England*, described "the brutal indifference, the unfeeling isolation of each in his private interest," which people experienced in the British capital, and stated that "the dissolution of mankind into monads of which each one has a separate principle, the world of atoms, is here carried out to its utmost extreme" ([1845] 1958, p. 24).

Against the atomization and "egoism" of society, as Saint-Simon called it, the social critics proposed a new order based on association, harmony, altruism, and, finally, the word that superseded all of these—socialism. The idea of socialism has a long history in the utopian tradition; one can trace its roots back to the dream of returning to a golden age of social harmony or to the radical theological creed—expressed most vividly by the Anabaptists of the sixteenth century and the Levellers and Diggers of the seventeenth—of the equality of all men. But equality alone is not the essence of socialism. The heart of socialism is to be found in the idea of community and in the doctrine that men can realize their full potential and achieve human emancipation in community. By this touchstone, the seeds of modern socialism are to be found in Rousseau [see the biography of ROUSSEAU].

The theme of community is also the central theme of Fourier, Owen, Saint-Simon, and Marx. The first three sought to achieve it through the a priori elaboration of the theoretical elements of community. Marx, on the other hand, sought to realize it through the sphere of philosophy and what he held to be its material embodiment, the proletariat. It is in the phrase "the realization of philosophy," the end point of a process of history, and not in any alleged distinction between utopian and scientific descriptions of socialism, that the difference between Marx and the others lies.

Both Owen and Fourier sketched socialist utopias that were enormously attractive to individuals whose sensibility was repelled by the evils of industrialism. Each wanted to establish a small agrarian community that science could make practical—in effect, a withdrawal from society. Neither man had a sense of history or any realistic awareness of the politics of his time. [See the biographies of FOURIER and OWEN.]

Saint-Simon ("the last gentleman and the first socialist" of France) was a very different sort, and the customary inclusion of him with Fourier and Owen as a "utopian" is actually a disservice to a formidable intellectual, a disservice initially performed by Marx, who, although he derived many ideas from Saint-Simon, failed to see the implications of much of the French writer's thought. John Stuart Mill, however, clearly recognized Saint-Simon's contribution, remarking, in *Principles of Political Economy* (1848), that in the few years of its public promulgation, Saint-Simon's thought had sowed the seeds of nearly all the socialist tendencies. Durkheim considered Saint-Simon to be the father of socialism, as well as of positivism, and devoted a book to his theories. Although in the *Communist Manifesto* Marx cavalierly dismissed Saint-Simon as a utopian, Engels in his later years remarked that Saint-Simon's "breadth of view" and "genius" contained in embryo "all the ideas of later socialists which are not strictly economic." For what Saint-Simon presented is what we know today as the theory of industrial society, and his discussion of the nature of solidarity outlines the theory of occupational community which Durkheim later elaborated. [See the biography of SAINT-SIMON.]

It is not too much to say, following Markham (1952), that the Saint-Simonians were the most important single force behind the great economic expansion of the Second Empire, particularly in the development of banks and railways. Enfantin, the most bizarre of the Saint-Simonians, formed the society for planning the Suez Canal. The brothers Émile and Isaac Pereire, who promoted the first French railway from Paris to Saint-Germain, also founded the Crédit Mobilier, the first industrial investment bank in France, and the Compagnie Générale Transatlantique, whose first ships were named after Saint-Simon and his followers.

In the hands of some of his more zealous followers, Saint-Simon's doctrines were made to seem ludicrous. Yet his own insight was considerable, and it was the Saint-Simonians' more diffuse (but no less intense) belief in Marxism which gave that doctrine its command over so large a part of the world.

**Marxism.** The *Communist Manifesto* (Marx & Engels 1848) and the writing done in the thirty years following it make up the corpus of work that later socialists drew upon and associated with Marx [for a detailed discussion, see the biographies of ENGELS and MARX]. Relying on the political activities of Marx as well as on his judgments, the

diverse socialist factions sought to justify their own policies. Thus Lenin and the Bolsheviks found in the address to the Communist League of March 1850, and in Marx's *Critique of the Gotha Programme* (Marx & Engels 1875-1891), the justification of their revolutionary and insurrectionary tactics. From Marx's activity in Cologne in the early part of 1849 and from his inaugural speech to the Grand Council of the International Workingmen's Association (the First International), democratic socialists have argued that peaceful electoral change is possible in the achievement of socialism.

Marx envisaged a two-stage development in industrial countries that presaged the victory of socialism. The first was the democratic revolution; the second, the social revolution. By the "democratic revolution" Marx meant the victory of the middle classes over the remnants of the aristocracy and the clearing away of feudal remains to achieve the successful development of capitalist production and of political rights for all in the society. By the "social revolution" Marx meant the economic victory of the proletariat, who will take over the ownership of the means of production. From this point of view, England was the most advanced country and, therefore, presumably the one most ripe for socialism. Measured on the same yardstick, Germany, while developing industrially, was still lagging behind because the middle classes had failed to complete the democratic revolution; Russia was the least advanced, since the middle classes had failed to act at all, whereas the German middle classes had at least done something in 1848. In the socialist perspective, therefore, Russia was the country where a revolution was most imminent, since it had lagged so far behind and was only beginning to catch up economically. But before 1914 all orthodox Marxists expected this to be a bourgeois, rather than a socialist, revolution, since the working class in Russia was too small to sustain a socialist revolution and the economy was too "immature" for socialism. Against the populists and the anarchists in Russia who argued that the country could skip a social stage and usher in a socialism based in part on the old village *miry*, or communal holdings, the early Russian Marxists—Axelrod, Plekhanov, and Lenin—argued that socialism in Russia would have to await the development of capitalism and the creation of a sizable working class. Only at the beginning of the twentieth century did the thought occur to some Russian Marxists, notably "Parvus" and Trotsky—and later Lenin himself, when he was converted to the idea—that they could use the impending Russian

revolution to wrest power from the bourgeoisie and thus spark revolution in the advanced industrial countries. Before 1917, no Marxists thought that socialism would be possible in preindustrial or underdeveloped countries. The West was expected to lead the way.

What kind of socialism was supposed to emerge? What would society be like the day after the revolution? And what were Marxists supposed to do while waiting for the revolution? No political party can exist without a program that holds out the promise of immediate benefits. But as Schumpeter has pointed out, anything positive done or to be done in the vitiated atmosphere of capitalism was *ipso facto* tainted. Marx and Engels discouraged programs that involved constructive policy within the capitalist order because they smacked of bourgeois radicalism. However, when they faced the problem in 1847, they resolutely cut the Gordian knot. As Schumpeter put it: "The *Communist Manifesto* quite illogically lists a number of immediate objects of socialist policy, simply laying the socialist barge alongside the liberal liner" (1942, p. 317 in the 1962 edition).

The problem was to recur constantly throughout the political history of most of the European socialist parties. Should one make immediate demands or not? This issue was fought out, for example, within the American Socialist party at the turn of the century; and it resulted in such factions as the Reformists, and the Impossibilists, who declared themselves against any such program on the ground that it would dilute the revolutionary ardor of the masses. More important, the problem of reforms, and of what kind of reforms, had to be confronted by the various socialist parties of Europe in the 1930s—such as the British Labour party, the German Social Democratic party, and the French Socialist party—when they entered the government and even took over sole responsibility for running it in a capitalist society. As we shall see, many of these governments and countries foundered when the socialist governments discovered, for example, that *they* had no solution for the problem of unemployment under capitalism. The slogan "Socialism or Capitalism" had left them unprepared for the exigencies of the intermediate period. This is always the dilemma of social movements that live in a world but are not of it.

Gotha and Erfurt. Marx did, of course, distinguish between socialism and communism, in the sense that the first is a transitional period and the second the undefined realm of man's freedom. For this aspect of the idea of socialism, two documents are crucial—the *Gotha Programme* (see Marx &

Engels 1875-1891) and the *Erfurt Program* (see Kautsky 1892), two doctrinal statements of the German Social Democratic party.

In 1875, two German socialist parties, one dominated by followers of Ferdinand Lassalle, the other by Wilhelm Liebknecht and August Bebel, nominal followers of Marx, met in Gotha to create a unified socialist party. The program they adopted there was in the main a product of Lassallean doctrine, and in a private communication Marx wrote a searing critique of it. In 1891, the German Social Democratic party adopted the so-called *Erfurt Program* (named for the city where the party congress was held), which was written principally by Karl Kautsky, under the direct supervision of Engels; Engels then published the *Critique* for its historic interest, feeling that the *Erfurt Program* went beyond the criticism Marx had made of the Gotha document. But the *Critique*, in its tone and implications, was more revolutionary and radical than the *Erfurt Program*, and, predictably, the left-wingers in the socialist movement, beginning with Lenin, formulated their program from the *Critique*. It was in the *Critique* that Marx used the phrase "revolutionary dictatorship of the proletariat," which after 1917 provoked far more recriminatory debates between communists and socialists than any other words he wrote. The communists took it as a justification of the suppression of all political parties other than the true proletarian party under Soviet rule. The socialists insisted that the phrase applied only to temporary and special situations until a truly democratic state could be organized, and was nugatory in those situations where a peaceful transition to socialism, through the electoral process, was possible.

The inflammatory phrase does not appear in the *Erfurt Program*, nor does any statement of immediate aims or political demands. The program was intended as a full-fledged analysis of the tendencies of capitalism, from a Marxian point of view, and as a general discussion of the "cooperative commonwealth" of the future. The program assumes the recurrent Marxist theme: "Few things are . . . more childish than to demand of the socialist that he draw a picture of the commonwealth which he strives for. . . . Never yet in the history of mankind has it happened that a revolutionary party was able to foresee, let alone determine, the forms of the new social order which it strove to usher in" (Kautsky [1892] 1910, pp. 122-123).

On the forms of organization, the managerial problems of a socialist regime—how orders are to be given, who will give them, which industries are to be managed by workers directly, which by state

enterprises; in short, the practical problems that the Soviet state faced after the communists had assumed power—the program is completely silent.

Kautsky, who inherited Engels' mantle as the leading Marxist theoretician, was prompted only once to deal with the problem of the organization of production in a socialist society (but not with the structure of authority within an enterprise). In some lectures delivered and published in 1902 as *The Social Revolution*, he declared simply that the organization of production would follow the scope of the market.

For example, gas lighting is clearly a municipal business. The development of electric lighting and the transformation of power in mountainous regions makes the nationalization of water power necessary. This operates also to transform illumination from a municipal to a national business. Again the business of the shoemaker was formerly confined to the local market. The shoe factory does not supply simply the community, but the whole nation, with its production, and is ripe not for communalization, but for nationalization. The same is true of sugar factories, breweries, etc. (1902, pp. 115-116)

In fact, when Kautsky had finished with his itemization (transportation, railroads, steamships, mines, forests, iron foundries, machine manufactures), it was clear that almost all industries would be nationalized in the "proletarian regime." [See the biography of KAUTSKY.]

If one goes beyond these pedestrian problems, however, it is interesting that the *Erfurt Program* ends, curiously enough, on a note reminiscent of the young Marx and of that strain in German romanticism which looked back to the glory of Greece.

The blessed harmonious culture, which appeared only once in the history of mankind and was then the privilege of a small body of select aristocrats, will become the common property of all civilized nations. What slaves were to the ancient Athenians, machinery will be to modern man. Man will feel all the elevating influences that flow from freedom from productive toil, without being poisoned by the evil influences which, through chattel slavery, finally undermined the Athenian aristocracy. And as the modern means of science and art are vastly superior to those of two thousand years ago, and the civilization of today overshadows that of the little land of Greece, so will the socialist commonwealth in moral greatness and material well-being the most glorious society that history has thus far known. (Kautsky [1892] 1910, p. 158)

#### Differentiation of the movement

The period from 1870 onward in western Europe saw the swift growth of industrialization and urbanization, the two crucial elements of modern

society. This expansion of industrial power and of economic growth and wealth, which was due largely to two technological innovations—the improvement of steel metallurgy and the application of electrical energy to factory, city, and home—seemed to confirm a number of Marx's predictions regarding the development of capitalism (see Marx 1867–1879, vol. 1, chapter 25, and vol. 3, chapter 23). Capitalism was undergoing remarkable changes. The expansion of the joint stock company (the prototype of the modern corporation) was forcing a separation of ownership and management, which in many areas resulted in the industrial manager's taking the place of the capitalist as the central person of the organization, and the large-scale enterprise began employing hundreds and even thousands of workers under a single roof. More important, the “amalgamation” movements of the 1880s and 1890s—the rise of trusts, cartels, and monopolies—and the consequent elimination of hundreds of smaller businesses seemed to bear out Marx's predictions about the centralization of capital and the socializing of the processes of production.

Volume 1 of *Capital* was published in 1867, and the subsequent expansion of the volume, along with its rapid translation into many languages, gave Marx, hitherto a neglected and cantankerous émigré in London, an authority in the international socialist movement, particularly in its German branch, which he had never had before. With the assiduous publication and spread of Marx's works by the growing socialist movements, Marxism suddenly became a vogue as no other socialist doctrine had ever been; and with the proliferation of followers and propagandists who in newspapers, pamphlets, and street meetings proselytized the simplified works of Marx, the doctrine itself assumed a canonical status that was unprecedented in the history of secular writing.

**The Second International.** In 1889 almost four hundred delegates from twenty different countries (three-fourths of them from Germany and France) met in Paris to create a new International, the Second International of socialist parties. The so-called First International, the International Workingmen's Association, was a loose confederation of small political and trade union groups, rather than parties, that had been organized in 1864. Although Marx was not the initiator of the First International, he quickly became its dominant intellectual figure, supplanting Mazzini, who had been asked to write its first draft program. The International broke up in 1872, when Marx and the anarchist leader Bakunin quarreled; though the anarchists

were expelled, Marx had the International's center moved to New York, preferring to bury it rather than allow some other group to capture it. The First International was formally dissolved in Philadelphia in 1876.

More than any other step, the founding of the Second International symbolized the swift rise of Marxist socialism in Europe. It was only 14 years earlier, in 1875, that the German Social Democratic party, the first socialist party in Europe, had been formed. In the next dozen years or so, socialist parties were organized in France, Austria, Belgium, Switzerland, Denmark, and Sweden. In Russia in 1883, the year of Marx's death, Georgii Plekhanov organized the first political group of Russian Marxists. About the same time, in England, M. H. Hyndman, the son of an aristocrat, organized the Social Democratic Federation, which, while calling itself Marxist, never acquired more than a small sectarian following; and a quixotic band of reformers organized the Fabian Society (the name alluded to the Roman general Fabius Cunctator—Fabius the Delayer—who was known for his patient, waiting tactics against Hannibal). In 1889, the year the Second International was founded, the historic *Fabian Essays in Socialism* was issued, with chapters by George Bernard Shaw, Sidney Webb, and Annie Besant. The book eventually sold two million copies, and laid the intellectual foundations of the British Labour party and of Labour governments for the next sixty years.

**Socialist parties.** By 1914, socialism had become the single most important political force on the Continent. In the 1912 Reichstag elections, the German Social Democrats amassed 4.5 million votes (over 30 per cent of the total) and 110 seats in the parliament, making it the largest single party in Germany. In France one of the socialist groups, the SFIO, garnered 1.4 million votes and 103 seats in the Chamber of Deputies. In Italy the socialists held over seventy seats in the parliament, and efforts were made to invite the party, or at least its right wing, into the government.

But the rise of the socialist parties was not only a simple matter of winning large numbers of votes, primarily among the working class. Within a new and growing system of universal political suffrage, it transformed the nature of the party system and the political structure of each country.

The political party of the first half of the nineteenth century was usually a loose association of “notables,” in Max Weber's terminology, invariably based on individual constituencies or districts, and often with little responsibility to an electorate.

With the growing democratization of the franchise in England, associations were formed in each district; and the caucus system, developed in 1868, enabled the Liberals to begin building local machines with full-time election workers. Yet mass membership was infrequent, and the parties of England, as well as the United States, depended for their finances on wealthy contributors. What the socialists did, particularly in Germany, was to introduce the disciplined and centralized mass party, with formal machinery for enrollment, regular payment of dues, a system of subscription to party newspapers and magazines, and, often, specified requirements of party activity. At its prewar peak, the German Social Democratic party had a million members and an annual budget of nearly two million marks.

But the socialist movement did more than build the first mass political party. It tried, in most of the European countries and to a lesser extent in England, to build a complete working-class culture, a social world of its own, independent of the official culture of the society. The German socialist movement, the model for all other socialist parties, built large consumer cooperatives (with a large wholesale organization and its own processing plants) as well as housing developments. By the 1890s there were national organizations of workers' athletic societies, workers' bicycling clubs, and workers' hiking clubs. In time, the workers' recreational and cultural movement extended into all fields from chess to the theater, where a strong *Volksbühne* (people's stage) was created. A working-class child could begin life in a socialist crèche, join a socialist youth movement, go to a socialist summer camp, hike with the socialist *Wandervogel*, sing in a workers' chorus, and be buried by a socialist burial society in a socialist cemetery.

If the idea of proletarian mountain climbing or socialist chess playing invites ridicule, one must see, as Carl Landauer (1959) points out, that the workers had been "excluded" from almost all accepted society, and they responded by creating their own.

**Revisionism and reformism.** The socialist movements at the turn of the century may have felt sure about inheriting the future, but there was considerable uncertainty as to when and how that inheritance would be realized. Marx, in all his writings, had never been specific about the road to power. After 1850 he felt that the day of the barricades was finished, not only for military reasons but also because bourgeois society would stabilize itself for a long time to come. Against this view, apocalyptic hopes occasionally flared up, as during

the Paris Commune. Yet Marx never took a dogmatic view as to any single course which the socialist movement would necessarily have to follow. In several instances, he felt that socialism might be achieved peacefully in the Western countries, where democratic institutions were being established. But he never ruled out the possibility of, and even the need for, violence, should the occasion demand it. Marx and Engels, throughout their lifetimes, insisted simply on the necessity of a revolution, by which they, as well as Kautsky, who became the leading spokesman for orthodox Marxism after the 1890s, meant a complete overturn of society once the socialists were in power—the abolition of private property, the end of social privilege, the breaking of the political and police power of the old ruling classes.

But the question whether this aim could be achieved by peaceful means was never settled. And this ambiguity was responsible for the major doctrinal conflicts that preoccupied the socialist movements from 1890 to 1914.

The major issues had to do with the themes of revisionism and reformism. Although their belief in socialism was never shaken, some individuals were skeptical that capitalist society was actually heading in the direction Marx had predicted. The standard of living was evidently rising rather than falling, and though some of the old middle class was disappearing, an emerging class of white-collar workers was taking its place. In many countries this new class did not wholly identify itself with the manual workers (with whom socialism was identified) or with the socialist parties. Most of all, the socialists' increasing success in parliament posed practical problems, such as entering the cabinets in coalition with other parties (and trying to put through social legislation rather than just waiting for capitalism to fall) and making alliances with nonworking-class parties such as the Liberals in England, the Catholic Center in Germany, or the Radical party in France. As James Joil has neatly put it: "By the end of the nineteenth century, no Socialist party could escape the difficulties presented by its own existence as a mass party, forced, for the moment at least, to function within a political system which at the same time it was seeking to destroy" (1955, p. 77).

**Germany.** The problem was especially great in Germany, whose Social Democratic party was the most theoretically intransigent, and it was first posed by Eduard Bernstein, who was the editor of the party journal and was chosen by Engels to be one of his literary executors. In 1899, Bernstein wrote *Die Voraussetzungen des Sozialismus und*

*die Aufgaben der Sozialdemokratie* (The Presuppositions of Socialism and the Tasks of Social Democracy), which triggered the debate. He argued, in effect, that the party should recognize the new changes in industrial society and declare itself to be what it was actually becoming—a party principally concerned with social reform. [See the biography of BERNSTEIN.]

Although Bernstein's arguments had some immediate political implications, the debate was conducted largely on a theoretical level. There were important doctrinal and historical reasons for this. The German movement had always set great store in theory as the guide to the future; and the discussion of theory—especially in a party isolated from the academic world—was in Germany a matter of status and prestige. But the debate on theory had important psychological roots as well. Although Marx had always tried to shape the course of the German socialist movement, his influence during most of his life was virtually nil. The first German Workers party was organized in 1863 by Lassalle, whose dandified manners and aristocratic pretensions infuriated Marx. The constitutional struggle between Bismarck and the liberal opposition dominated the political life of Prussia at the time; and to Marx and Engels, observing the situation from England, this struggle was an outward expression of the conflict between the historic forces of aristocratic feudalism and bourgeois capitalism. They therefore urged the new German Workers party "to drive the 'revolutionary' Liberals forward against the government, preparing at the same time to lead the proletariat in its turn against the victorious forces of the bourgeoisie once the feudal system had succumbed to their onslaught" (Morgan 1965, p. 8). But Lassalle and his followers were convinced that Prussian liberalism had no such revolutionary propensities and that the quickest way for the workers to increase their influence was to join Bismarck's campaign against his liberal opponents, hoping to win in return certain socialist demands—freedom of the press and association and, above all, manhood suffrage, which Lassalle and his followers felt was necessary to any further advance. Lassalle, under the influence of Louis Blanc, also hoped that the state would finance co-operative factories so that the workers could become their own employees and overcome the "iron law of wages" which kept them impoverished under capitalism. Lassalle, a Hegelian, believed that the state should rule society; and socialism, with state ownership of factories, was the embodiment of the ideal of the state. Against Lassalle (and his successor J. B. Schweitzer), the socialists

Liebknicht and Bebel organized a rival socialist party, known as the Eisenachers. Nominally Marxist, the Eisenachers were primarily an anti-Prussian party, and though they adopted the program of the International Workingmen's Association, they did so largely for tactical reasons against the Lassalleans. In practice they operated as a broad "people's party." The war of 1870 and the subsequent unification of Germany dissolved most of the issues between the two factions.

The debate remained on a theoretical plane for good practical reasons. Reformism—which assumed that effective parliamentary power could be obtained—was impossible in Germany; for while imperial Germany had a parliamentary system, decisive power was actually in the hands of the emperor. Any chancellor needed the Reichstag's approval for legislation and for the budget, but a chancellor could be replaced only if he lost the confidence of the emperor. The chancellor, in fact, was responsible not to the Reichstag but to the crown. The government, though constitutional in form, was in fact autocratic. And while social democracy was growing in parliamentary strength, there was no corresponding growth in the powers of parliament.

Thus the political system barred the Social Democrats from any legitimate hopes of winning power through parliamentary means and reinforced the rhetoric of revolutionary intransigence. The "fatal mistake," as Schumpeter called it, was Bismarck's. In a Machiavellian stratagem, he introduced universal suffrage in the federal empire after 1871, in the hope of winning the peasant votes, and to some extent those of the workers, against the urban middle classes. When the socialist vote began to increase, Bismarck introduced restrictive legislation against the socialists as a party, while introducing a comprehensive set of social welfare measures in order to win the loyalty of the workers. The maneuver failed. When the antisocialist laws lapsed in 1890, the socialists emerged stronger than ever, and their experiences reinforced their antagonistic temper and revolutionary rhetoric.

By the turn of the century, and thereafter, the party controlled large municipal administrations, was supported by a powerful trade union movement, and had a vast bureaucracy of its own. The party's ideology no longer corresponded to its sociological reality (Michels 1911), but, because the political system did not allow the party to discard its revolutionary rhetoric, the ideology remained intact.

Thus, when Kautsky came to answer Bernstein, he couched his polemic in the language of Marxist

scholasticism. In practical fact, the situation confronting the Social Democratic party of Germany—as well as the socialist parties of the Austro-Hungarian Empire and czarist Russia—was the failure of the bourgeoisie, as far back as 1848, to complete their middle-class political revolution and eliminate the structures of monarchy and aristocratic rule. But Kautsky offered no program to deal with this problem other than the rhetorical formula of revolution and the relentless march of history which would sharpen the crises of capitalism.

When in 1918 all three empires—Germany, Austria-Hungary, and Russia—collapsed, the socialist parties in these and other countries all adopted widely varying courses. Although capitalism by the turn of the century had become the predominant *economic* form of Western society, political structures and cultural traditions varied widely from one country to another. Paradoxical as it seems in Marxist terms, the cultural elements, more than the economic conditions in each country, account for the varying forms the socialist movement took. As Schumpeter remarked, every country had its own socialism.

*England.* In Germany a rigid class structure, reinforced by a militaristic code of honor, excluded the workers from society and led to a counter stiffness of doctrinal Marxist orthodoxy. In Great Britain, by contrast, the intelligence of an old gentry class, a deep tradition of liberty and of political rights, the lack of a militaristic tradition and even of a standing army, the long-established supremacy of Parliament over the monarchy, and the deep-rooted empirical conception of politics, which rendered ideological “all-or-none” terms distasteful—all made for a civil polity, one that accepted the existence of the socialist movement as a legitimate part of British society.

The British Labour party came into being in order to realize the rights of the working class in the society. The exemplar of peaceful—and piecemeal—social change, it was never Marxist, though it was based on strong class feeling and class loyalty. The sources of this position are threefold: There was, first, the deep and persistent strain of nonconformist Christian evangelism, which saw equality as a moral imperative. (The writings of R. H. Tawney, principally his books *Equality* [1931] and *The Acquisitive Society* [1920], which helped to shape the English socialist outlook, reflect this evangelism.) There was, second, the influence of the Fabians, principally Sidney and Beatrice Webb, who, representing one aspect of the Benthamite tradition, were social engineers for whom socialism was a tidy answer to the waste

and disorder of the capitalist world. And third, there was the large trade union movement, which saw in the Labour party a means of influencing the course of favorable legislation.

Whereas the Continental socialist parties participated actively in the affairs of the Second International, the British Labour party, before World War I, remained insular and rarely tried to impose its influence, as the Germans did, on other socialist parties. Much of this was due to the general isolation of the British from Continental social thought (one rarely encounters a discussion of “the state” in English political theory), which in turn has to do with the British temperament. As G. D. H. Cole, who knew Webb well, wrote:

Sidney Webb's first thought in dealing with any question he took up was to find an administratively workable solution; and apart from a very few essentially simple ideas—he did not trouble himself much about underlying philosophy. He was fully convinced that the trend of events in the modern world was towards Socialism, and that this trend would continue: so that he saw no need to put himself into revolutionary opposition to the main course of development. . . . He had what is sometimes called a “civil service” mind—that is, a habit of translating every idea into terms of the machinery needed to give it effect. . . . He was, however, impatient of dreamers, and uninterested in theories which he could not turn into practical schemes. (Cole 1953–1960, vol. 3, part 1, p. 210)

H. G. Wells summed up still another side of British socialism when he left the Fabian Society after a personal falling-out with Shaw and the Webbs. He caricatured all of them savagely in his novel *The New Machiavelli*. “Her soul was bony,” he wrote of the character named Altiora Bailey (Beatrice Webb). “If they [Altiora and her husband] had the universe in hand I know they would take down all the trees and put up stamped tin green shades and sunlight accumulators. Altiora thought trees hopelessly irregular and sea cliffs a great mistake.” The root image of their world, Wells wrote, was “an organized state as confident and powerful as modern science. . . . Individualism meant muddle, meant a crowd of separate undisciplined little people all obstinately doing things jarringly each one in his own way. . . . The organized state would end muddle forever” (Wells [1910] 1927, p. 193).

The Webbs spent most of their lives making detailed empirical inquiries into problems of social welfare and administration. While Marxism is usually associated with the idea of planning, Marx, as we have seen, never drew any specific blueprint of a planned society. Nor did the German Social Democrats, despite their large parliamentary rep-

resentation, even study industrial organization and indicate what they might do if they came into power. The Webbs and the Fabians, however, issued several hundred tracts providing detailed expositions of Labour thinking on both the local and the national levels. One can appreciate the thoroughgoing detail of Fabian research from a series of studies (conducted between 1898 and 1901) about the municipalization of different services—alcohol traffic, milk supply, pawnshops, slaughterhouses, bakeries, hospitals, and fire insurance (see Cole 1953–1960, vol. 3, part 1, pp. 215–216). In 1909, the Webbs's minority report on the operation of the poor laws set out in comprehensive detail the conception and policy of the welfare state (Great Britain . . . 1909). Later studies dealt with the general problems of the organization and control of industry. [See the biography of WEBB, SIDNEY AND BEATRICE.]

The Fabians operated primarily as an elite group and never sought a large membership. Their influence was felt through their published ideas, their research, and their propaganda. Before World War I, the Fabians were a constituent group in the Labour party; but in keeping with their avowed tactic of permeating all institutions of society that had the power to influence policy—the civil service, the professions, business groups, and local government—they drew upon all groups, nonsocialist as well as socialist, for help. After 1918, when the British Labour party adopted a new constitution and accepted as its basic program a Fabian policy statement drafted by Sidney Webb, relations between the Fabian Society and the Labour party became closer.

The Labour party has been unique among socialist parties, not only because of its open emphasis on "gradualism" but also because of its structure. Unlike the Continental socialist parties, based on individual membership, the British Labour party originated as a federation of unions and constituent socialist societies, and its funds were raised principally through levies on the union members. Until 1918 individuals could not become members directly. They became affiliated with the Labour party either through membership in the Independent Labour party, the Fabian Society, or the trade unions, and policy was worked out in negotiations between these organizations. Candidates were nominated by agreement between the unions and affiliates, on a roughly proportional basis. The individuals elected to Parliament then formed the parliamentary Labour party.

After 1918 the membership system was changed in order to organize local Labour parties directly

in each constituency, but the federated structure remained. The formulation of policy has therefore been a complicated affair. Since the trade unions have traditionally constituted the largest group in the party and vote en bloc in the Labour party conventions, the annual Trades Union Congress is an important arena for adopting resolutions. The annual Labour party conference of unions, affiliates (such as the consumer-cooperative movement), and local constituency parties sets policy. But this policy is only morally binding on the parliamentary Labour party. In office, the Labour party is responsible only to the parliamentary party, not to the Labour party as a whole. In this crucial respect, once again, the British Labour party is shaped by the structure of British politics and not by the conventional theories of socialist organization.

*France.* In England, the transition to a modern industrial society was accomplished peacefully by the economic, and to some extent social, blending of the rising plutocratic groups with the gentry, while a set of political compromises brought all sections of the country, including the working class, into the society. In Germany, the older feudal elements, using the state, had created powerful industries and maintained a political hegemony over the subordinated middle class. The working class, excluded socially, had built its own institutions, but paradoxically these very institutions had facilitated the integration of the workers into the society.

France lacked any such unifying features. Economically, it was a two-sector society with a large peasant and artisan class alongside a modern industrial economy. Politically the feudal structure had been broken, but the bourgeois parties were never able to establish their unambiguous control; the unstable balance of forces periodically opened the way to an adventurer attempting to seize power. The working class itself was split.

In Germany and England, the trade unions were part of the organized socialist movement because they hoped to achieve most of their aims through political concessions by the government rather than through direct economic bargaining. But in France, the trade unions were completely independent of the socialist parties. One wing, the syndicalists, based their gospel on Proudhon's anti-authoritarian and antipolitical ideas, and their anti-parliamentary bias on the betrayals of the 1848 revolution and the Commune. The French form of union organization, the Bourses de Travail, which stressed the local community of all trades rather than the nationwide organization of one industry or craft, expressed the tendency to create a new society of labor rather than to concentrate

on wages and working conditions. The other wing was that of "political socialism," but here, too, many of the temperamental weaknesses of French politics—its tendentiousness, its hyperbolic rhetoric, and its instability—were apparent in the French socialist movement.

In 1896, there were no fewer than six national socialist parties in France, each usually more interested in fighting the others than in fighting the opposition. By 1905, the six had been reduced to two national parties, one led by Jules Guéde, who was the spokesman for orthodox Marxism and whose following was chiefly in the industrial north, and the other by Jean Jaurès, a former professor of philosophy and a renowned orator—a humanist repelled by the aridities of Marxist dogma—whose following was among teachers, skilled workers, and intellectuals attracted to the idea of ethical socialism.

Under the pressure of the Socialist International, the two parties made an uneasy union, but the factions were still unable to agree on whether to enter coalition governments headed by bourgeois parties. The French parliamentary system, with its emphasis on multiparties, made it difficult for any single party to assume power. The art of government was the art of coalition. As socialist parliamentary strength rapidly increased, the socialists faced the problem of silently abstaining, thereby allowing rightist cabinets to govern, or entering center-left coalitions. Those who opposed coalitions argued that the assumption of governmental responsibility would weaken the militancy of the workers and would force the party to agree to non-socialist programs. Those who favored coalition, originally named the Possibilists, argued that in government, socialists could more easily defend the republic against reactionary forces—and at the same time help pave the way to socialism.

**Syndicalism.** If the British Labour party and Fabian gradualism together represent one end of the socialist continuum, revolutionary syndicalism, with its faith in direct action and the general strike, represents the other. The word "syndicalism" simply meant "unionism," but in the period preceding World War I it connoted an antiparliamentary, antireformist tendency deeply rooted in the Proudhon anarchist, antipolitical, antiauthoritarian tradition.

Revolutionary syndicalism was primarily a phenomenon of the Latin countries—France, Italy, and Spain—though syndicalist elements made a strong showing in the British labor movement among the seamen and the transport workers, and in the United States among the western miners

and loggers of the Industrial Workers of the World ("Wobblies"). Syndicalism never took hold in central Europe, the heartland of orthodox Marxism.

Marx and Engels had taught their followers to regard syndicalist tendencies as an expression of backwardness and immaturity, as a passing phase in the development of industrialism which would disappear after the emergence of the large-scale factory system and a modern industrial proletariat. Whatever the validity of that appraisal, syndicalism as it emerged in France was not only a despairing rebellion against industrial capitalism but, in its vision of the future, a protest against the destruction of free trade unionism under an authoritarian state socialism.

This aspect of syndicalism was formulated by Fernand Pelloutier, a journalist who had been active in the various Marxist movements in France. Disillusioned with the political parties, which were preoccupied with obtaining office and power, Pelloutier felt that the only protection workers could have against arbitrary managerial power—either in nationalized industries or in capitalist enterprises—would be workers' control of industry.

Syndicalism was important less as a doctrine for reorganizing society than as an attitude. It was hostile to parliamentary methods—and in 1905 the French trade union movement, in the famous Charter of Amiens, laid down the principle of strict independence from all political party involvement. Its injunction has been so strong that, unlike every other European trade union official, no French union secretary was allowed to take a parliamentary seat. The charter proclaimed the general strike as the instrument of revolution, a single collective action whereby the entire working class, by laying down its tools, could halt the operations of industry and in that "transforming moment" take power. Further, the charter glorified spontaneity rather than organization; and it emphasized the role of a conscious minority, an elite of revolutionary proletarians whose task it would be to lead an aroused working class into revolutionary action. [See *SYNDICALISM and the biography of SOREL.*]

**Guild socialism.** The syndicalist emphasis on workers' control has had recurrent appeal in working-class and radical movements. In Great Britain, where the "medievalist socialism" of William Morris and John Ruskin, firmly against industrialism and statism, caught on for a time, syndicalist ideas had a strange efflorescence before World War I in the "guild socialism" of A. R. Orage and G. D. H. Cole. [See *the biography of COLE, G. D. H.*]

The guild socialists, reacting against the administrative socialism of the Fabians, blueprinted a

decentralized socialist society in greater detail than any other socialist movement had. Politically, the guild state was to be a bicameral body—the one a geographical parliament based on local constituencies, the other a “functional” body made up of representatives of each trade or industry. The consumer, through Parliament, was to set the goals of production (e.g., the division between consumption and investment, the priorities of development); the Council of Guild Representatives, the producers, was to be responsible for the efficient management of industry. Each guild was to be a self-governing body, based on local councils, and was to set its own conditions of work. Each guild would receive money in proportion to its membership, but would pay wages in accordance with its own rules—either in equal shares or in differentials according to skill. Thus a national political and economic planning system was combined with the idea of cooperative workshops.

**Russian populism.** The course of world politics since 1917 has been dominated by the long shadow and the doctrinal pronouncements of Vladimir Il'ich Uli'ianov. Before 1914, however, Lenin played only a small role in the affairs of international socialism. He was a member, after 1905, of the bureau (executive committee) of the Second International, one of 69 persons representing 23 member countries. He was known personally to the leading figures of the socialist movement, but his works, not yet translated, were little known; and as an exile representing one of several fiercely quarrelsome sects, he carried little weight in the International.

Moreover, none of the prominent theoreticians of Marxism expected a socialist revolution in Russia: there was only a small industrial proletariat, and the country was still backward and feudal. In accordance with the theory of “necessary” stages of social development which Georgii Plekhanov (1883) had posited in founding the Marxist movement in Russia, this vast country still had to pass through the stage of capitalism, and the bourgeois middle-class democratic revolution was still to come. Once Russia could be led along the lines of Western social development, then political freedom, trade union freedom, and legal socialist activity would be achieved; after the democratic revolution, which was the role of the middle classes, would come the social revolution, in the more distant future. In effect, Russia was still “before 1848.”

Yet the revolution did occur and was shaped by certain peculiar features of Russian social history. Before socialism, the dominant radical tradition

in Russia had been populism, a doctrine associated in large measure with that remarkable exile Alexander Herzen. Herzen saw in the peasant communes the seeds of a future cooperative society that could bypass the harsh and disruptive effects of capitalism. From London, Herzen kept alive the liberal spirit of the Russian intelligentsia through his magazine *Kolokol* (The Bell), and in his home were to be found the major exiles from Russia.

The populism preached by Herzen idealized the peasantry and asserted, in almost mystic fashion, that the peasant was the source of wisdom and virtue. In the summer of 1873, roused by the appeal of Mikhail Bakunin, hundreds of students went to the countryside to “go to the people” and rouse them to action. Students disguised as workmen wandered the countryside, preaching revolution, but the peasantry, suspicious of their would-be saviors, simply turned them over to the police.

The episode was important in the history of populism, and its lesson was drawn most starkly by Peter Tkachev, one of the theorists of Russian populism. Insisting that the peasants as a mass—the people—were incapable of revolutionary creativeness and that only a “conscious minority”—the intelligentsia—could make the revolution, Tkachev sketched the kind of organization that would be necessary. It would have to be, he argued, a conspiratorial one, based on the principles of centralization of power and decentralization of functions. And it would have to be led by the intelligentsia. These two themes—the need for compact organization and the role of a revolutionary elite—were to bear fruit some twenty years later in the thinking of Lenin [see the *biography of LENIN*].

### Socialism between the world wars

The war that had begun in the summer of 1914 not only brought revolution to Russia; it signaled the collapse of international socialism. For several years the heat and lightning of war had flashed in Europe, and each time the international socialist movement had proclaimed its readiness to strike in order to prevent international conflagration. Its growing power seemed to assure a new foundation for the maintenance of peace. Yet in 1914, with very little dissent, the socialist parties of Germany, Austria, and France all voted to support their governments in the war. The German Social Democrats, the most powerful socialist party in the world, had in the past publicly dissociated themselves from the German state. And the Kaiser, in turn, had once called them “fellows without a country.” Now, with only one dissenting vote, the

parliamentary party gave full support to the budgetary war credits the government requested. There were tiresome quotations from Marx in support of the action: Marx had supported the principle of nationality; Marx had once proposed support of Germany in a war against Russia; and in 1891 Engels had said that in such a war Germany would be fighting for its national existence. Once scripture was being cited, the French party had its own rationalizations, heavily laden with quotations from Marx. So did the Austrians. The fact remained that when the crisis finally came, nationalism as an emotional idea proved to be stronger than class, and international solidarity proved to be a myth. The International was at an end.

**Polarization of belief.** The period between the two world wars saw Europe torn apart by the conflicting ideologies of communism and fascism. In the process, democracy and the socialist movement were the losers. Italy, Germany, Austria, and Spain came under fascist or authoritarian leadership. Even earlier, right-wing dictatorships took over Portugal, Hungary, and Rumania. Belgium and France were threatened by strong fascist movements. Only Great Britain and the Scandinavian countries were relatively free of these storms, though a small fascist group arose in England. The sociological reasons for these variations in fortune will be discussed in this section.

The October Revolution in Russia had brought before the European socialist movement the insurrectionary idea of the seizure of power. For more than forty years the idea had been an abstraction to the socialist movement. Lulled by the "inevitablism" preached by Engels and by the steady growth of electoral success, the socialist movements had assumed that at some distant time it might yet be necessary to seize, or at least to maintain, power that had been established legally; but no one took the idea seriously. Even inside Russia the idea, while fiercely debated, had an air of mimetic combat. Plekhanov had argued that men could act only insofar as social conditions allowed them to do so, i.e., only within the limits of the "laws" of history. But Lenin had apparently demonstrated the primacy of "will," at least within disorganized situations wherein a small group of determined men, acting skillfully and in disciplined fashion, could seize power.

Within Marxian theory there were actually three successive versions of the theory of taking power. The first, later presented in Lenin's "What Is to Be Done?" (1902), conceived of the proletariat as directed by a small group of professional revolutionaries drawn from the middle-class intelligent-

sia; the working class would support the middle-class revolution in the faith that there would be a second round wherein the proletariat—supported in Germany by a peasant revolt—could take over. But this conception passed with the end of the revolutionary wave of 1848–1850; and as industrialization and a new appraisal of the nature of factory life and the role of the proletariat emerged, a second version appeared. Now the emphasis was placed on the building of mass political parties led by workers who had achieved theoretical competence—typified in Germany by Bebel, who had been a carpenter, and in England by Keir Hardie, who was a miner. It was now felt that socialism need not come through insurrectionary tactics or coups led by small bands of professional revolutionaries, but peacefully, through parliamentary means or even simply in a show of strength.

After 1905 a few socialist theorists had argued that a new stage was emerging. These included Rosa Luxemburg, a Polish-Jewish intellectual with doctorates in philosophy and jurisprudence; Herman Gorter; Anton Pannekoek, a Dutch astronomer; and A. L. Helfand, a Russian-born economist who wrote under the name Parvus. Each of these socialists was influenced by developments in the Western labor movements rather than by events in Russia. In her book *The Accumulation of Capital* (1913), Luxemburg tried to extend Marx's economic doctrines by arguing that after a phase of imperialism, in which capitalists would seek to export capital surpluses, the capitalist system must inevitably break down and create a crisis. [See the biography of LUXEMBURG.] Gorter and Pannekoek had been close to anarcho-syndicalism, and Rosa Luxemburg and Parvus (in his early years) had been active in the left wing of the German social democratic movement. In one way or another, they all insisted that with the growing education of the working class, there would develop, during a crisis, a revolutionary spontaneity in the masses, and that to insist on party hierarchy and professional leadership would only lead to a dictatorship by the leaders.

**The Third International.** It was only after the Bolshevik victory in 1917, and the creation of the Third (Communist) International, that Lenin's earlier text was canonized in order to claim for the Bolsheviks a unique revolutionary knowledge and thus to enforce the hegemony of the Russian party over all other Communist parties.

Lenin summoned the revolutionary working-class groups to a conference, which met in Moscow on March 2, 1919, for the purpose of organizing the new International. Its main objectives

were the immediate seizure of power by working-class parties in Europe, the abandonment of false bourgeois democracy, and the establishment of a dictatorship of the working class for the systematic suppression and expropriation of the exploiting classes.

There was an apocalyptic fervor in the air. World revolution seemed palpably near. Shortly after the first congress of the Communist International, a Soviet republic was proclaimed by Béla Kun in Hungary, and another in Bavaria by left-wing socialists. It seemed as if the only thing needed to carry out a successful revolution was steely revolutionary will. A second world congress of the Comintern (the shorthand name for Communist International) was convoked in Moscow in July 1920. It was no longer a small gathering; delegations came from parties in a dozen countries.

The chief feature of the meeting, which gave organizational shape to the international communist movement, was the drafting of 21 points as conditions for membership in the Comintern. The purpose of these points was to create in each country a disciplined, conspiratorial party whose chief purpose would be to combat the old socialist leaderships and to assert the binding, from-the-top-down, authority of the Comintern over each national party. Throughout Europe and in the United States, such socialist leaders as Ramsay MacDonald in England, Kautsky and Rudolf Hilferding in Germany, Morris Hillquit in the United States, and Jean Longuet in France had opposed participation in the war and had taken a "middle" position against the reformists. But in the opinion of the new Comintern, these leaders had to be rejected and exposed as much as those of the right wing, and had to be fought just as bitterly. The 21 points commanded communists to split every socialist party and trade union in the world, to organize an underground machine in addition to the public activities of the party, to disorganize as much as possible the army of each country, and to reject any cooperation with "social patriots and middle-group people."

By 1923 the revolutionary tide had receded all over Europe. The communists had completely misread both the character of the labor movements of western Europe and the social structure of those societies. For a short period the communists engaged in adventurism and even in putschism: the Red Army marched into Poland to advance the revolution, only to be defeated by Pilsudski, once a nationalistic socialist, who a few years later set up an authoritarian regime; insurrections were

planned, in 1923, in Saxony and Thuringia; and an abortive uprising in Hamburg failed. But after 1923 it was clear that, for the time being at least, Europe had achieved some measure of political and economic stabilization. The Soviet Union itself turned, under Lenin, to the problem of what to do with power in a single country. The large Norwegian Labor party, as well as such syndicalist leaders as Jack Tanner in England and Alfred Rosmer and Pierre Monatte in France, withdrew from the Comintern because of the centralization of party structure. What was left in Europe was the wreckage of the socialist movement in half a dozen countries and the fear of revolution that drove the middle classes to support right-wing groups. Within the Comintern, the hegemony of the Russian party was complete, and within a short time the International itself became principally an arm of Soviet foreign policy, rather than an independent instrument of revolution. [See COMMUNISM, *article on THE INTERNATIONAL MOVEMENT.*]

The sharp turn to the left in the Soviet Union in 1929, and Stalin's effort to consolidate his rule by turning on his erstwhile right-wing political allies, coincided with a world-wide economic depression and the rise of fascism in Germany and other countries. For the communists these events heralded the final crisis of capitalism, and they awaited a fresh wave of revolutionary activity. After an analysis of fascism in Italy, communist theorists argued that fascism was the last stage of monopoly capitalism; and since it could not solve the inherent contradictions of the capitalist crisis, inevitably the revolution was again at hand. From this analysis the communists concluded that the chief obstacle to their victory was not the capitalists but the socialists, who still "misled" the majority of the working class. In several instances, the communists even worked with the Nazis in order to diminish socialist influence. They voted with the Nazis in the Prussian Landtag to bring down the Social Democratic government. They cooperated with the Nazis in the Berlin street-car strike in 1932 in order to increase disorder in Germany.

**Socialists in government and opposition.** The communists thus became the implacable enemies of the democratic regimes in central and western Europe; and the middle classes in many countries, principally Italy and Germany, out of fear of the left and because of economic crises, often voted for the extreme right. However, an important element contributing to the weakness of the democratic regimes was the inability of the socialists, owing to the contradictory attitude toward capital-

ism and democracy inspired in them by Marxian dogmatics, to provide any effective leadership or support for democratic societies.

In 1931 the reconstructed Socialist International consisted of parties with more than six million dues-paying members. The total parliamentary vote for socialist candidates was almost 26 million. More than 1,300 socialist deputies sat in the parliaments of their countries. Some 360 daily newspapers spoke for the labor movement. Yet, remarkably, this large force was almost completely paralyzed when the crises occurred.

The root problem was an old one. The socialist movement, true to its Marxist heritage, did not believe that capitalist society could be reformed. When the socialists, particularly of the right wing, were thrust into office because of the failure or the unwillingness of any other party to rule, they followed the most orthodox of economic policies, because "the crisis has to run its course." Believing, from a Marxist point of view, that the reason for the depression was a disproportion in growth between the producer goods sector and consumer goods sector, they tried to use up the resultant "overproduction" so that a better proportion between producers' and consumers' purchasing power would emerge, leading to an upswing.

As Adolf Sturmthal has pointed out in *The Tragedy of European Labor* (1943), the socialist movement, with all its strength, was basically a pressure group seeking social concessions from the state for the immediate benefit of the working class. But it had neither an economic program nor any clear idea of planning. State intervention arose out of unorthodox economic theories, such as John Maynard Keynes's in England and Gunnar Myrdal's in Sweden, or the unorthodox financial policies of Hjalmar Schacht, who had been made president of the Reichsbank by the German socialists when Hitler began the rearmament that revived the German economy. Nowhere except in Sweden, and later in the planning ideas of Hendrik de Man, did the socialists have any idea of what to do about the depression [see the biography of MAN].

*Italy.* The socialists, in a different way from the communists, also misread the nature of fascism. For example, fascism was barely mentioned in the major report of the 1928 International Socialist Congress on the political situation in Europe. It was seen as an idiosyncrasy of the Italians; and its ideology, emotional roots, and irrational quality were not understood. Yet Italy did foreshadow quite clearly the fate of the other nations in central Europe.

Shortly after the war, Italy seemed on the verge of a proletarian revolution. In the general election of 1919 the socialists won two million out of a total of 5.5 million votes, and the leadership of the party had passed into the hands of the left wing, which openly asserted that the next step would be the "creation of a Socialist Republic and the establishment of a proletarian dictatorship." Workers had spontaneously begun to seize factories, and the peasants of Sicily and the south had appropriated the uncultivated holdings of absentee landlords. As Sturmthal put it: "Continuous unrest, strikes, factory occupations, expropriation of land—all this convinced the middle class that a revolution was impending and that the democratic middle-class state was powerless to stave off the danger. Public opinion became more and more convinced that a strong man was needed to establish law and order" ([1943] 1951, p. 182).

The decisive, dramatic incident occurred in August 1920, when a wage dispute in the metal industries led to sudden "stay-in" strikes in which 500,000 workers occupied the factories, kept the machinery going, and assembled arms to resist evacuation. Workers in other industries called on their leaders to order the taking over of other factories. But the socialist leadership, divided and uncertain, hesitated; and finally a pact was reached with the industrialists whereby the employers agreed in principle to the union's demand for workers' control of production. This was the high point of the revolutionary tide, and then a new force appeared, the Fascists.

Organized by Benito Mussolini, a former leader of the left wing of the Italian Socialist party, the Fascists preached anticapitalism, nationalism, and the necessity of violence. With his *squadristi*, Mussolini went into the streets to break up working-class meetings and to beat up working-class leaders. In 1921 an effort was made to form a socialist-liberal coalition government and save the country from the threatened civil war. The right-wing socialists made the proposal, but the idea was vetoed by the left wing. By 1922 a form of civil war had spread in Italy. In the large urban industrial centers of the north, strongholds of the socialist movement, the city administrations passed into the hands of Mussolini's *squadristi* through terror and intimidation. Bologna, Genoa, Livorno, Milan, and finally Naples were taken over by the fascists. A general strike called by the trade unions on August 31, 1922, failed ignominiously, despite the united support of the labor movement; and middle-class opinion swung even more strongly to the

fascists. At the invitation of the king, and with the support of the army, bureaucracy, and big business, Mussolini was invited to become premier. For two years he ruled by parliamentary means, but after the assassination of Giacomo Matteotti in June 1924 and left-wing withdrawal from the Chamber of Deputies as a moral protest, Mussolini became more openly dictatorial: trade unions, political parties, and cultural organizations were either disbanded or placed under fascist control, and local autonomy was abolished. By 1926 parliamentary government had vanished. [See FASCISM.]

*Germany.* In November 1918, the Germany of Wilhelm was no more. The Kaiser had abdicated, and Friedrich Ebert, a former saddlemaker who was now the head of the Social Democratic party, installed himself as head of the new republic. But the socialists themselves were split into three factions. The "majority socialists" represented the right wing of the party. The "independent socialists," led by Kautsky and Bernstein (together for the first time in twenty years), had opposed the war and now favored a radical program of economic reform. The extreme left, led by Luxemburg and Liebknecht, knew that the German republic was going to be a middle-class state and wanted to organize a proletarian party prepared for an eventual revolutionary opportunity. But younger socialists took over the left wing en masse, overruled Luxemburg and Liebknecht, and began to prepare the "Spartacus group," as the left wing called itself, for immediate revolution.

In this situation the attitude of the majority socialists was decisive. The Workmen's and Soldiers' Councils, which had sprung up spontaneously on the Soviet model, elected the majority socialists to the leadership of the new Council of People's Commissars. But the majority socialists feared a repetition of the Russian chaos and sought first to achieve stability with the cooperation of some of the military.

When the Spartacus group initiated a rebellion in early 1919, it was put down by Gustav Noske—the majority socialist appointed as commander-in-chief of the army—with the help of the Free Corps, created and led by former imperial officers. After the uprising was quashed, Free Corps officers cold-bloodedly murdered Liebknecht and Luxemburg, who had loyally supported their comrades despite their opposition to the venture. When, in the spring of 1919, left-wing socialists—and later the communists—took over the newly proclaimed Bavarian republic, the Free Corps was used to take Munich and to murder hundreds of the insurgents,

thus seriously reducing the authority and prestige of the socialists. In March 1920, Reichswehr troops led by a little-known nationalist named Wolfgang Kapp mutinied and marched into Berlin. The republican government could not muster enough loyal troops to defend the capital, and fled to Stuttgart. A powerful general strike, joined by all the factions, defeated the putsch in four days. When Kapp was routed from Berlin, communist-led workers in the Ruhr tried to continue the general strike. The newly formed Weimar coalition—majority socialists, the Catholic Center, and Conservative Democrats—sent the Reichswehr into the Ruhr to crush the revolt.

In the end the majority socialists, as well as the republic, were the losers. In the general elections of June 1920, the majority socialists and the middle-class parties of the Weimar coalition lost heavily, and the nationalist parties gained. A new cabinet consisting of the Catholic Center and the right-wing German People's party took office. It was clear that on the right as well as on the left the republic itself had only shaky support among the German people.

The socialists were given one more chance. In May 1928 the German Socialist party, now reunited because the independents refused to accept the *Diktat* of the Comintern, emerged as the strongest party in the Reichstag. Although they lacked an absolute majority, the socialists took office, with Herman Müller as chancellor and Hilferding, the famed socialist theoretician, as minister of finance. But a year later Germany, along with the rest of the Western world, was plunged into the depression, and the socialists had no economic policy to meet the crisis. Hilferding, mindful of the ruinous inflation of the early 1920s, followed an orthodox deflationary policy which reduced purchasing power and increased unemployment. The strength of the labor movement defeated the employers' efforts to reduce wages and salaries; the fault, however, lay not with the employers, who had to reduce production costs or get out of business, but with the state, which had failed to work out any active policy. Instead of tapping idle capital funds, the government worked above all to balance the budget, or at least to reduce budget deficits, even if this meant reducing unemployment insurance benefits. Several German socialist economists favored devaluation or the abandonment of the gold standard, a monetary policy later associated with Keynes. But they were opposed, on the ground that this would lead to economic and political nationalism. In all essentials the socialists followed

a policy of laissez-faire: the depression had to "run its natural course." After all, as any Marxist knew, capitalism could not be reformed.

*England.* A similar dilemma confronted the British Labour party. In 1918 it had adopted a socialist program for the first time; the new social system was described as a thing that would emerge gradually out of capitalism, by a series of piecemeal changes. The Labour party was then still weak, third in size after the Conservatives and the Liberals. Five years later, following a prolonged period of unemployment which the Conservatives had been unable to cope with, the Labour party emerged as the strongest English party and, supported by the Liberals, in January 1924 formed the first Labour government in British history. The government carried out some modest social reforms, but its tenure was short. When the British Foreign Office published the so-called Zinoviev letter, a set of instructions from the head of the Comintern to British communists on antimilitarist tactics—a letter now conceded to be a forgery—the electorate voted strongly Tory, and the Labour government was ousted.

The trade unions, disappointed by their failure in politics, turned to more militant economic action. The coal miners, always the most militant, had a genuine grievance—their wages had recently been cut. (The problem was one of government monetary policy; in 1925 England returned to the gold standard at the prewar pound-dollar exchange rate, and the prices of British exports were above the world market level.) The miners, refusing to accept the wage cut and demanding the nationalization of industry, went on strike in May 1926. With the support of the entire trade union movement, this strike soon widened into a general strike, the first in English history. Railwaymen, local transport workers, builders, printers, iron and steel workers, all walked out, almost completely paralyzing London and other parts of Great Britain. The strike had had no revolutionary aim—its only purpose had been to support the miners—but when the government stood firm, the unions, uncertain of their next step, retreated. After nine days the general strike was called off, and its main result was that the left wing lost influence and the right wing gained complete control of the labor movement.

In June 1929 the British Labour party had its second chance. In the general election of that year, the party won 287 of the 615 seats in the House of Commons and, with the support of the Liberals, formed the second Labour government, with Ram-

say MacDonald as prime minister. But the problem that soon confronted the German socialists was already bedeviling England. Though other countries at the time were still enjoying prosperity, England, because it could not compete in world markets, had a great deal of unemployment. The Labour government was pledged to make far-reaching social reforms; the business community demanded reduced taxes and a retrenchment in social policy. A collision was inevitable. One way out would have been devaluation or strict exchange controls to keep gold from leaving England. Either course would have been an acknowledgment of the end of Britain's domination of the international economy—which she had maintained for almost a hundred years—and a new policy of economic nationalism. This the Labour government refused to do.

When the depression hit England full force, the Labour government had its back to the wall. The flight of capital from London had become a flood, and the Bank of England warned that unless the budget was balanced, the pound would fall. In orthodox fashion, the Labour government was committed to free trade and to defense of the gold parity of the pound. MacDonald proposed, as an economy measure, to cut unemployment benefits; and when the trade union elements in the party rejected such a cut, or any reduction in social services, MacDonald split the Labour government and, taking 14 colleagues with him, formed a national coalition with the Conservatives and the Liberals. The national government itself failed to stem the tide, and in September 1931 Britain went off the gold standard, introduced protectionism and a tariff, and began, under a Tory government, to set up economic dikes in an effort to save itself from the floods of world-wide depression. The Labour party, though it still retained some strength among the electorate, suffered a great loss of parliamentary strength—from 287 to 52. For nine years it sat in opposition until it joined the Churchill government of national unity in 1940. In 1945, for the first time in its history, the Labour party won a clear electoral majority.

*Austria.* In February 1934, after four days of bloody fighting, the reactionary regime of Engelbert Dollfuss destroyed the Austrian social democracy. This was a blow that struck the international socialist movement especially hard, for Austrian social democracy had been the model for all proud socialists. It was a disciplined party and had the support of almost all of the working class. Its leaders and theoreticians, particularly Friedrich Adler and

Otto Bauer, had been respected for their courage and their contributions to socialist thought. The party, while revolutionary in its aims, maintained a sanity and realism in political affairs which had prevented it from imitating the adventurism of the Hungarian communists in 1919 or the feckless policy of the German Social Democrats. In 1927, at the peak of its strength, the Austrian Socialist party polled 42 per cent of the total electoral vote, and in Vienna the socialists won a majority of almost two-thirds. Half a million of Vienna's two million inhabitants were dues-paying party members, and the city was a showcase of municipal achievement. In 1919 the socialists had joined with the Christian Social party in a coalition that gave the country stability and permitted sections of the old Austro-Hungarian Empire to achieve their independence. The first president of the Austrian republic, Karl Seitz, was a socialist, as was its first chancellor, the noted legal scholar Karl Renner.

The problem of the Austrian socialists was twofold: their strength was entirely in the urban areas, while the surrounding countryside and the middle classes supported the Christian Social party; and Austria was under direct and steady pressure from Italy to crush the socialist movement and establish a fascist regime. When the Nazi vote began to increase in Austria, as a result of Hitler's prestige and his direct aid to the new Nazi party of Austria, Dollfuss, a Catholic, was faced with the choice of coming to terms either with the Nazis or with the socialists. With the support of Mussolini (who wanted an independent Austria as a buffer against Germany), Dollfuss suppressed both the Nazis and the socialists. But the defeat of the socialists meant that the Austrian government had lost its main hope of independence. Four years later Kurt von Schuschnigg, who succeeded Dollfuss when the latter was assassinated by the Nazis, invited the underground socialists and the trade unions to support him against the Nazis. However, while negotiations were going on, Nazi troops invaded Austria and the country was annexed by Germany.

*France.* Only in France, among the major countries of western Europe, was a fascist threat—that of Colonel de la Rocque and the Cagoulaards, the right-wing group supported by the army—beaten back. In June 1936, a socialist government headed by Léon Blum took office. It was the first time that the party officially entered a coalition government, but it did so—also for the first time—with the support of the communists, who had abandoned their cry of "social fascism" and now proclaimed the need for a popular front to resist

fascism. Within a year a French New Deal had been inaugurated. The trade unions, never before recognized by French employers, now were granted collective bargaining rights. A social insurance system was established for the first time. Through public works and wage increases, Blum tried to increase the purchasing power of the workers and, thus, to restore prosperity. But, curiously, Blum resisted the idea of economic planning, fearing that it was essentially "statist" and fascist in character. Caught between the rejection of capital exchange controls by its political allies, the Radicals, and the communist opposition to devaluing the franc, the first Popular Front government fell.

*Sweden.* Only in Sweden did the socialists have any real success, and they achieved it by abandoning the orthodox economic policies that the German Social Democratic and British Labour governments had followed. In 1932 a Swedish labor government was formed for the first time. It decided that balancing the budget on a year-to-year basis made little sense and that the government itself had to intervene in the economy. The government embarked on a set of extensive public works and financed these endeavors not by taxes, which simply would have shifted the existing purchasing power, but by borrowing money from idle capital funds. Public investment during a depression had to be expanded to compensate for reduced private spending. By following a steady policy of economic expansion, the Swedish government managed to eliminate unemployment by 1938. Five years earlier it had been as high as 164,000. These "Swedish stepping stones to full employment," as A. P. Lerner described the process (1944), wholly unorthodox at the time, have become commonplace economic practice in almost all Western countries.

The rest of the melancholy story of European socialism before 1939—the Spanish Civil War, the Soviet purge trials and the Hitler-Stalin pact—while crucial to the history of Europe, is less relevant to the discussion of socialist theory and doctrine.

## Socialism since World War II

*Revisionism and peasant revolution.* In the theory and practice of socialism after 1945 there were two completely unexpected developments. One was the rise of "revisionism" in the communist countries and movements of Europe. That is, the highly centralized command economies were modified by the trend toward a market and profit system, dogmatic ideology was eroded and tended to be replaced by pragmatic and instrumental pol-

icies, and force and violence were discouraged as a means of fostering revolutionary change in non-communist countries. In fact, with the extension of planning and public control in the noncommunist countries of Europe as a parallel to the growing decentralization of planning in communist countries, some theorists have argued that a "convergence" was taking place between the communist social systems and those of the West.

The second development was the rise of the peasantry as a revolutionary force—or at least as a presumed revolutionary force—in colonial countries, bolstered by a new theory that the revolutions in the last third of the twentieth century would be made not by the proletariat, which had lost its élan through *embourgeoisement*, but by the peasantry. For the peasants were now, in the words of the "Internationale," the wretched of the earth. Marx, in many of his writings, had scorned the peasantry as intrinsically reactionary and small-minded because of its preoccupation with private property; he used the phrase "rural idiocy" more than once. But modern methods of communication and a network of trained political cadres have since the 1920s been able to weld the peasantry into an active political force. The Chinese Communist party under Mao Tse-tung, following the destruction of its urban base of support when Chiang Kai-shek smashed the Shanghai commune in 1927, had reorganized itself as a peasant party and had won power by enlisting peasant support. Fidel Castro, though a middle-class intellectual, made his revolutionary appeal through the peasantry, while the Cuban working class, including the communist-dominated trade unions, "coexisted" tacitly with the dictator Batista. In Algeria, in South America, in Vietnam, the peasantry, not the urban working class, became the focus of revolutionary appeal.

The spread of socialism as word and doctrine, especially in the years after World War II, presented itself as a paradox, particularly in terms of the original intention and predictions of Marx. It was assumed by Marxists that the triumph of socialism would occur first in the industrialized countries, as a result of the contradictions and crises of the capitalist economic system; but this triumph has taken place primarily in backward countries and in agrarian societies. Marxism was an ideology of protest *against* the course of industrialization, but it has become, instead, the ideology of industrialization; not a creed of social justice, welfare, and the equitable distribution of products, but a rationale for centralized controls, postponement of consumption, and rapid economic growth.

Since the Soviet Union embodied these developments, it became an important model for many of the new states that were seeking to embark on the difficult road of industrialization. The Stalinist regime had apparently succeeded in transforming Russia from an agrarian country into an industrial one. Despite enormous waste during collectivization, it had achieved high rates of economic growth, and its successes were most dramatically symbolized by the technological achievement of being the first nation successfully to launch man-made vehicles into outer space.

**Socialism in western Europe.** In the West, the socialist movement saw the complete triumph of what, in classical doctrine, would be called reformism. During the war against fascism, almost all the socialist parties had joined the governments of national unity, either at home or in exile. The sense of the nation and democracy took priority over the ideas of class and capitalism. In the Western countries, the labor and socialist parties had become completely of their societies, as well as *in* them.

One can identify five features, common to almost all the socialist parties of western Europe, which marked this new practice and doctrine:

(1) The complete abandonment of the idea of revolutionary methods and violence as a means to power; the complete acceptance of parliamentary means; and the complete readiness to participate in nonsocialist coalition governments. The anguished theoretical debates which had earlier split the French, Belgian, Austrian, and other parties on the question of entering "bourgeois governments" had vanished.

(2) The transformation of the socialist and labor parties from *class* parties, speaking only for working-class interests, to *people's* parties seeking a more inclusive concept of general welfare. In some instances, as in Germany, there was the realization that as a working-class party the Social Democrats would be consigned to being a permanent minority; in other instances, as in England, there was the recognition that the changing class structure of society, particularly the rise of a technical and salaried middle class, made it imperative for the Labour party to speak for these social groups as well as for the working class.

(3) The recognition that the definition of socialism as a social and economic ideal was inseparable from the idea of democracy, both as a means and as an end. The Marxist concept that lingered through the 1930s—that democracy was a "bourgeois" concept and only a mask for class rule—was rejected. By democracy as a means, the socialist parties meant the full guarantee of the rights

of free speech and free assembly, and the maintenance of political rights for the opposition. As an end, democracy was defined as the free consent of the governed.

(4) The surrender of the idea of nationalization or state ownership of the means of production as a "first principle" of socialism, and the substitution of public control of enterprise and planning as the means of achieving economic growth and equitable incomes. The sectarian orthodoxy that within a capitalist state one could not plan for social ends was replaced by the theory that governmental powers could be used for the gradual transformation of the economy and that a "mixed economy" of public and private enterprise was the most desirable solution.

(5) A complete opposition to totalitarianism. While the socialist movements had long been in ideological opposition to communism, what the new attitude meant, in practice, was support of the military and political aspects of the Atlantic Alliance against the Soviet bloc and an identification with the national interests of each Western country, through NATO, against Russian expansionism. Nothing, perhaps, more strongly revealed the degree of change than the choice of Paul-Henri Spaak, once the firebrand leader of the Belgian left, as secretary-general of NATO.

*Germany's Social Democrats.* Most of the transformed socialist attitudes were expressed at the Frankfurt Congress of 1951, which symbolized the revival of the Socialist International. Although no longer the powerful voice of a confident movement or the platform for thunderous international pronouncements, the Socialist International still provided some doctrinal identification for those who still called themselves socialists. Its Declaration of Principles, unanimously adopted, stated the new common conceptions of socialism almost a hundred years after the initial statements of the First International, as formulated in Marx's inaugural address of 1864.

"Socialism," the declaration reads, "aims to liberate the people from dependence on a minority which owns or controls the means of production. . . . It aims to put economic power in the hands of the people as a whole and to create a community in which free men work together as equals" (Lowenthal 1951, p. 113).

Private versus public control remains the decisive contrast, but private control is not identified with private ownership, nor public control with state ownership; and the phrase "exploited classes" has been superseded by "the people." Democratic planning becomes the basic means for the creation

of socialism, and public ownership is regarded as only one of a number of different means, to be used where necessary. "Democratic socialism," says the statement, "therefore stands in sharp contradiction both to capitalist planning and to every form of totalitarian planning; these exclude public control of production and a fair distribution of its results" (*ibid.*).

Democracy, in this revised credo, is not only a means to the achievement of socialism—a "favorable battleground for the class struggle," as the older view had it—but an integral aspect of socialism itself. "Accordingly," as Richard Lowenthal put it, "the conflict between democratic socialism and communism no longer appears as a disagreement about means to a common end, but as a conflict of fundamental ends between the adherents of a democratically controlled economy and the defenders of the despotism of a managerial bureaucracy" (*ibid.*).

Nowhere is the change more striking than in the new program of principles adopted in 1959 by the German Social Democratic party in Bad Godesberg. The German SPD had long been a reformist party, but its very adherence to outworn dogmas, as we have seen in its attitude toward the possibility of reforming capitalism in the 1920s and 1930s, crippled its ability to act realistically in economic and political affairs. But the Bad Godesberg program rejects the very idea of Marxism. The name of Karl Marx and the concept of Marxism are missing from the declaration of principles, and terms like "class" and "class struggle" are carefully avoided.

In modern political analysis, party programs are rarely taken seriously. Usually they are formal documents, paying lip service to expected pieties that historically made the parties' activities legitimate. But, as F. R. Allemann points out:

The German social-democracy is a "programme party" of the first water: in its history of nearly a hundred years it has always attached the greatest importance to basing its policy on a solid system of principles laid down in a fixed programme rather than merely on the urgent issues of the moment. In this respect at least it has remained true to its Marxist tradition: in its view any political action that is intended to influence and transform society must be based on an analysis of that society. (1960, p. 67)

This was the view that guided the formulation of the *Erfurt Program* in 1891; it is the view behind the Bad Godesberg declaration of 1959.

The overriding idea in the Bad Godesberg program is that a modern industrial society cannot be ordered by a single uniform principle. Common ownership is recognized as a legitimate form of

public control, but the analysis centers not on property but on economic power, which must be subject to public control. For the first time a socialist party states explicitly that private ownership of the means of production is entitled to "protection and promotion" so long as it does not hinder the construction of an equitable social order. The idea of subjecting the entire economy to central planning is rejected, and the party accepts the free market, wherever there is real competition. The basic formula is "as much competition as possible—as much planning as necessary," and the SPD not only describes free consumer choice and the free choice of place of employment as "all-important foundations" of freedom, but lauds free competition and entrepreneurial initiative as important elements of Social Democratic economic policy. The economic pattern envisaged is that of a "mixed economy" in which the private profit motive has a place and in which the control of great economic power is the central task of a libertarian economic policy.

In line with the lessons of the previous twenty years, particularly those of the Soviet experience, the party declared that the problem of economic power cannot be settled simply by transferring power from private hands into that of the state. Being dependent on an uncontrolled state bureaucracy is not necessarily better than being subject to private capitalist power. The conclusions, however, are rather vague: common ownership is to be "organized according to the principles of self-government and decentralization," and in the managerial structures "the interests of the workers and employees must be represented just as much as the public interest and that of the consumers" (*ibid.*).

The aim of the new socialist program is a plural society, and this idea extends not only into economics but into the cultural sphere as well. Thus the party refrains from proclaiming any "ultimate truths" and states that neither a state nor a political party should have any power in religious and philosophical spheres. As Allemann says, "Marxism set out both to 'interpret' and to 'change' the world." The German Social Democrats, having rejected the myths behind the ideology of socialism, no longer "claim to provide a universally valid philosophy nor do they believe any longer that their policy is in accord with the irrevocable laws of social dynamics" (*ibid.*).

*Britain's Labour party.* The British Labour party never had German socialism's attachment to world philosophy, and its sense of crisis was less severe. The wellsprings of evangelical feeling, ex-

pressed in a strong commitment to equality and social justice, still provide the emotional justification of socialism for the English Labourites; but a different problem has confronted the leadership. Socialism, as it was accepted in the West, had been a singularly distributivist doctrine. It presumed that capitalism had solved all the problems of production and that its failures had to do with social injustice and inequality. But the problem of economic growth was found to persist in all social systems. How does one step up the rate of output and increase production without overt controls and coercion, and without inflation?

In 1945 the British Labour party, for the first time in its history, won a majority in Parliament and assumed sole charge of the government. For six years it ruled, and during that time it laid down the permanent foundations of a welfare state in England. Social services were extended, and for the first time a comprehensive system of medical care was established. A number of basic industries, principally coal, railways, transport, and steel, were nationalized; but, to the dismay of the government, nationalization did not provide any automatic answers to the problem of growth. Coal and railways had been sick industries, but the Labour policies, although they helped maintain full employment, did not materially increase the productivity of these industries. In 1951 Labour was voted out of office and replaced by a Tory government. Its defeat caused the British Labour party to ponder its program. In office it had exhausted the "intellectual capital" inherited from the early Fabians. What would it do if it was voted into power again? The major task of intellectual renovation was attempted by C. A. R. Crosland in his book *The Future of Socialism* (1956), which became the working text for Hugh Gaitskell, the new leader of the party. Crosland's main argument was that the Labour party must give up the shibboleth of nationalization and, in economic matters, promote the modernization of industry in whatever social form it could best be done, whether private or public. The main content of socialism, Crosland said, is not economic but social: to seek an equitable division of wealth by reducing the role of inherited property as the means of achieving a privileged place in the society; and to erase social class distinctions, by a major reform of the educational system. Only by releasing talents which remain unfulfilled, because of the social class system, could Britain eventually find new vigor in its industry and its culture.

For the traditionalists in the party, both left and right, the Crosland-Gaitskell vision smacked of

heresy. An effort on Gaitskell's part to eliminate clause four—which pledges the party to nationalization of industry as a major doctrinal tenet—from the British Labour party constitution, was rebuffed. Gaitskell died before the British Labour party was again voted into power in 1965, but the revisionism he espoused had clearly taken hold in the party.

*Italy's Socialist party.* The one socialist party in the West which maintained a traditional left-wing line was the Italian. Forged in exile and deeply conscious of the intense class heritage of Italian workers, the Italian Socialist party, led by Pietro Nenni, maintained an electoral alliance with the communists for more than ten years, and still vaguely preached the class struggle. A small group of moderate Socialists, led by Giuseppe Saragat, split away from the Italian Socialist party in 1947 to join the coalition government led by the Christian Democrats.

The Khrushchev disclosures in 1956 of Stalin's misdeeds, the Soviet intervention in Hungary in the same year, the general disillusionment with communism, and the growing feeling in Italy that no effective role could be played without entering a coalition government eventually led Nenni, in 1963, to join a center-left coalition and finally, in 1966, the two wings of Italian socialism were reunited.

Whatever the socialists in Italy, or in any of the Western countries, could offer, it was no longer the old certitudes of doctrinaire Marxism. Few of the parties had any sure answers about how to build a new social order. All that remained was a lingering vision—and hope.

*Socialism in the "third world."* To speak of the *tiers monde* as a sociological entity is to group together geographical areas that are vastly different in their historical and class structures and similar only in their poverty, their instability, and, in most cases, their quest for modernization.

The area encompassed by north Africa and the Middle East, from Morocco to Egypt and Syria, was the cradle of ancient civilizations, an area ceaselessly marauded by invading armies for thousands of years. Its populations have absorbed a great jumble of genetic strains, and in the last several hundred years the mixture of Arab, Turkish, and European (French, English, and Italian) cultures has blended into a cosmopolitan *mélange*. It is a world with a small, westernized, intellectual elite, a strong, traditional religious structure, and a vast mass of poor peasants. Southeast Asia has an array of old societies and ancient empires which, in most instances, were held together after the departure

of the former colonial rulers by a thin administrative class, trained by these rulers, while the political parties or military regimes learned how to govern. Africa south of the Sahara is a motley collection of tribal societies grouped in political areas that were carved out by the old imperial powers. These areas were almost never formed on a basis of indigenous unity, and there has been no educated or technical class available for the many complex tasks of government and economic development.

The social structures of these areas are vastly different from those of Europe, and it is difficult to see where Marxist categories could be applied. In south and southeast Asia, primordial relations of blood, religion, language, or tribe are expressed as communal attachments; and nations have been split by ancient ethnic, tribal, caste, regional, and religious differences. India has Muslim-Hindu divisions, caste lines, secularist-traditionalist splits, and ten major linguistic divisions. Burma, since gaining its independence, has been plagued by insurrections of the Shan, Karen, and Kachin peoples, split by linguistic, religious, tribal, and regional differences. Ceylon's Sinhalese and Tamil communities differ in language, race, caste, and religion. Indonesia has the classic division between the central island, Java, and the outer islands, as well as a secularist-Islamic controversy. The Malay states are split between the Chinese and the Malays, and the disunity is compounded by indigenous tribal groups in Sarawak and Sabah.

In Africa, within the predominant tribal societies, there has been little class differentiation, since most of the land has been held collectively and life has been led communally. But between tribes there has been grisly hostility, and the rectification of borders between the new nations provides grist for conflict that will go on for generations. In the Islamic world, in countries as divergent as Morocco and Pakistan, theocratic structures are fused with the political and administrative apparatus, and this fusion in turn shapes a distinctive social structure.

The major tasks which most of these countries have set for themselves are modernization and industrialization. How far modernization necessarily must upset the traditional and religious values of a society is a question that divides sociologists. But it is clear that in many of these countries the new elites are seeking to upset or supplant the traditional values, often because the source of their own authority or of their routes to power rests on different criteria. In these countries socialism is often seen as the means of creating new, modern-

ized states. Since the end of World War II, Arab socialism, African socialism, and Asian socialism have emerged as new ideological flags and new socioeconomic forms.

The socialism of these new elites is vastly different from the traditional visions of the nineteenth-century socialist prophets, intellectuals whose ideologies were universalistic and humanistic. The new ideologies are parochial, instrumental, and largely the creation of political leaders. While the driving forces of the old ideologies were social equality and political freedom, economic development and national power inspire the new ideologies.

Socialism appeals to the new elites in a number of ways: as a doctrine, it identifies them with a historical-progressive movement; as an ideology, it seeks to create an identity that can transcend tribal and communal boundaries; and as a social system, it concentrates power in the hands of the elites, providing for the nationalization of the basic industries of the countries and their direction under some ministerial control. Although the socialism of the West has come to favor decentralization and a mixed economy, the socialism of the new states focuses on central planning, state ownership and direction of enterprises, and one-party regimes. Socialism, in effect, serves as a means of mobilizing the society for industrial and social transformation. [See MODERNIZATION.]

*The Middle East.* No socialist movement of the Middle East calls itself, as the Western movements did, the representative of the working class. These movements, not only in fact but often in theory, are based on an alliance of the new middle class (largely salaried state employees), the peasants, and the workers, with the middle class openly taking the lead. To the extent that a theory of representation exists, it is based on an undifferentiated general will. In practice, the effort is being made to give nationalism a social content.

This is clearly the case with the socialism of Gamal Abdel Nasser, in the United Arab Republic. Before he came to power in 1952, there had been no large-scale socialist movement in Egypt. (The Egyptian Socialist party was in fact fascist.) Nor had Nasser and the army group he represented ever espoused socialist ideas. But once he was in power, his proclaimed "Six Objectives of the Revolution," plus his opposition to foreign business, led him increasingly to speak of his socialist faith. In 1954 he declared: "We consider that the state has tutelage over both private and public property and the responsibility for the protection of the individual against all economic and social exploi-

tation" (Halpern 1963, p. 244). In 1956, after the abortive Anglo-French-Israeli invasion of Egypt, Nasser appropriated the Suez Canal and foreign banks, insurance companies, and export firms. By 1962 he had nationalized all large Egyptian enterprises, expanded land reform, and placed all important sectors of the economy under the control of socialist planners. Democracy, the Egyptians were told, would come only gradually.

Egyptian socialism is not based on any mass or cadre party. Rather, it is being installed from the top down, through the initiative of a small technocratic elite whose support is largely military. Whether it can survive its first, charismatic leader is a moot point, because, lacking a social base, Egyptian socialism has not been able to institutionalize its reforms.

The other major socialist movement in the Middle East is the Arab Socialist Resurrectionist party, commonly called the Ba'ath party. Organized in Syria in 1953 as a merger of two smaller parties, it declares itself "a national, populist, revolutionary movement fighting for Arab unity, freedom and socialism." Its nationalism is not restricted to any particular Arab state, but to the Arab people as a whole, and it is against "all other denominational, factional, parochial, tribal or regional loyalties." Its socialism, in the words of its programmatic statement, seeks the "guarantee [of] the continuous growth of the nation in its spiritual and material development; and it will guarantee close brotherliness among its individual members" (*ibid.*, p. 240). Full of rhetoric about revolution and struggle, the Ba'ath party has said little about the concrete steps it would take to achieve socialism. Like many such movements, it is seeking to develop a new faith to supplant the traditional creeds. Islam is never mentioned by name; the implication, as Halpern points out, is that it belongs to an earlier era. In practice, the Ba'ath party, caught in the nationalist rivalries between Egypt, Syria, and Iraq, has split accordingly.

*North Africa.* In north Africa the socialist creed has been fashioned largely by French-educated native intellectuals, and it assumed a revolutionary coloration, particularly in the late 1950s, through the vigorous movements for independence from France. In Algeria, where the struggle was most bitter, the FLN (National Liberation Front) was composed mainly of Algerian trade unionists (most of whom worked in France and contributed money to the struggle), middle-class elements, and Berber nomads. After Algeria became independent, Ahmed Ben Bella, surrounded by various Marxist and Trotskyite advisers, sought to introduce

workers' self-management in industry and to collectivize Algerian farms. But as a result of the flight of French technicians and agronomists, Algeria was soon in severe economic trouble; and Ben Bella's efforts to solidify his personal power led to a coup by his ally, Colonel Houari Boumedienne, who controlled the army. Boumedienne pledged to continue "Algerian socialism," but his program was the typical drab mixture of statist enterprises and private landholdings characteristic of so many other new states. For the French left, ironically, Algeria had in the meantime become the emotional symbol of a "new awakening" of the underdeveloped world. Frantz Fanon, a Negro psychiatrist born in the French West Indies and educated in France, renounced his French citizenship during the Algerian civil war and wrote a new Communist manifesto, *The Wretched of the Earth* (1961), which preached the necessity of violence as purification. Fanon also praised the noble qualities of the peasantry, still uncorrupted by bourgeois values—unlike the European working class [see the biography of FANON]. For Jean-Paul Sartre and other leftist intellectuals, the Algerian war was a crisis of conscience in which they declared their civil disobedience against the French state. Yet the revolution ended in tawdry factionalism and a gray, repressive regime.

A quieter path to socialism was taken in Tunisia in the 1960s by the Neo-Destour party, later renamed the Socialist-Destour party. Led by Habib Bourguiba, a French-educated lawyer, Tunisia became independent in 1956, without the fierce violence of Algeria. A one-party regime was installed, and it proceeded to nationalize the major enterprises of Tunisia and to develop a planned economy. The Socialist-Destour movement is actually a middle-class party, and the trade unions are firmly subordinated to the state. Bourguiba, as the charismatic leader, has imposed a vigorous cult of personality on Tunisian society—numerous streets, monuments, enterprises, and other public activities are named for him. It is still a "first-generation" country, and it remains to be seen whether it can institutionalize its new reforms and maintain a stable political structure without undue group conflict when Bourguiba is succeeded.

*Sub-Saharan Africa.* The 1960s have seen the mushrooming of a new doctrine, largely unknown even five years earlier, which African leaders call African socialism. The meaning of the phrase, however, is very difficult to pin down (Friedland & Rosberg 1964). Few African socialists have any idea what they mean concretely by socialism. President Léopold-Sédar Senghor of Senegal, for ex-

ample, who has tried to provide a framework in his book *African Socialism* (1959), sees socialist humanism as a combination of Marx and Engels with Teilhard de Chardin, in which the Jesuit paleontologist-philosopher's ideas of "corpusculization" and "complexity" (the effects of outer and inner gravity in creating an increasing complexity of matter) are joined with the dialectic to create "the general law of complexity-consciousness." Whether it is the quasi mysticism of Senghor, trying to create a new definition of man, or the tough-sounding Marxism-Leninism of President Sékou Touré of Guinea, seeking to join the idea of a cadre party with the "communaucratic" values of precolonial African society, the idea of African socialism is one of pure rhetoric—a language to impress, to inspire, to intimidate—rather than a set of guidelines for specific action. Its usefulness is hortatory rather than instrumental.

What "African socialism" means to these countries is the effort to be distinctive and modern, to assume some special character in the contemporary world, and, in a more prosaic way, to deal with the problems of social identity, economic development, and new class formations in the emerging societies.

The problem facing most of the new states in Africa—31 black African nations gained their independence in the decade between 1955 and 1965—is to find some unifying symbols beyond parochial and local identities in order to instill a sense of pride and action in their people. If many citizens of these new states have little feeling of nationality, they have nonetheless found some kinship through the idea of being African. African socialism has been a new myth, something to take the place of the anticolonial passions that fueled many of the independence movements. Seeking a specific content for African socialism, its ideologists have stressed the indigenous character of the communal ownership of land, the egalitarian character of the society, and the extensive network of social obligations which ties clans together. Thus, it is argued, capitalism and private property are "unnatural" to Africa.

But though the indigenous elements of traditional society have been present in Africa, there still remains the crucial question whether such institutions can carry over into the complex, modern industrial society that these countries want to build. By and large, most African countries committed to the idea of socialism see the government as exercising the primary responsibility for accumulating capital, directing investment, and building an infrastructure for the society. The im-

mediate practical difficulty is that Africa has had no large entrepreneurial class of its own from which modern talent can be drawn. The only large non-European commercial and manufacturing class, particularly in east Africa, has consisted of Indians; and because of their clannishness and their ties to the mother country, they are regarded as unassimilable or as aliens. Nor do most African countries, except perhaps Nigeria and a few others that were under British rule, have a sufficiently large number of administrators, engineers, or managers. Another dilemma is that the capital accumulation for most African countries is dependent on earnings from agricultural and other primary products, and these are subject to sharp fluctuations on the world market or are dependent on the good will of the advanced industrial countries; and good will is a notoriously frail foundation on which to build an economic policy.

Many countries seek a way out by industrialization. But rapid industrialization, if at all possible, involves a large-scale transformation of the farming class (which in most African countries is between 80 and 90 per cent of the population), new class distinctions, and new social group tensions, either between different interest groups or between populations that have become urban and cosmopolitan and those that have remained local and parochial.

Senghor, when he turns to practical matters, says that Senegal must proceed slowly. As he wrote in *African Socialism*: "We have rejected prefabricated models . . . we have observed that formulas like 'priority for heavy industry,' or 'agrarian reform' have no magic power within themselves; applied dogmatically, they have produced partial failures. That is why we established priorities as follows: 'infrastructure, rural economy, processing industry, heavy industry,' in line with reasonable requirements and our realities" (1959, p. 157). In keeping with this ordering principle, Senegal has earmarked a substantial part of its budget for "social development," by which it means health and hygiene, municipal administration and housing, and education. The economy as a whole is not socialist, but mixed: communal in agriculture, a public-private combination in utilities, and private in banks, commerce, and industry.

Under Kwame Nkrumah, Ghana set out vigorously to create a socialist organization of the economy. While private capital was invited, particularly for the construction of the Volta Dam, state enterprises predominated in banking, manufacturing, construction, fishing, forestry, and electric power. But the ambitious schemes ran far ahead of the

reality. The trade unions protested the squeeze on wages. Capital reserves and foreign exchange were squandered. Grandiose and costly projects—presidential residences and palaces, as well as the large-scale Pan-African political headquarters—were built at enormous expense. One-party rule became more and more authoritarian: opponents were jailed or murdered, the courts were reorganized to stifle their independence, and the freedom of the university was abridged, while Nkrumah's decrees became increasingly personal. In 1966, while Nkrumah was traveling abroad, a revolt by the army ended his regime.

Most African countries have found that their major problems are primarily political: to maintain that fundamental stability which will allow any planning, economic or otherwise, to proceed. The initial glittering promises made by the first generation of political leaders have not been realized. Within the first decade of independence, military coups racked half of the new nations, and in the others rigged elections and strict bans on opposition have kept the initial regimes in power. For these countries the tensions of social change, and the need to create institutional mechanisms to deal with them, constitute the major problem confronting the societies. A Kenya White Paper of 1965 on African socialism and its application to planning in Kenya, said soberly that socialism, even the socialism of a welfare state, would be a long time in coming. The immediate need was to transform the economy from a subsistence to a market economy; to develop land and to introduce modern agricultural methods. Nationalization, since it does not always lead to additional resources for the economy as a whole, would be used only when other means of control were ineffective. The commitment is to socialism as an ideal, not as an ideology (Harris 1965).

*South and southeast Asia.* In January 1953, representatives of a dozen Asian socialist parties met in Rangoon for the first Asian Socialist Conference. The principal Asian figures—Jayaprakash Narayan and Asoka Mehta of India, Ba Swe and Kyaw Nien of Burma, Sutan Sjahrir of Indonesia—were internationally renowned. Leading Western figures came as fraternal delegates: Clement Attlee, the former Labour prime minister of England, headed the delegation from the Socialist International, and Milovan Djilas the one from Yugoslavia.

At this time, the governments of half a dozen countries—India, Burma, Ceylon, Indonesia, Cambodia, and Singapore—described themselves as socialist, for socialism was the predominant ideology of the area. It seemed that socialism in Asia

was making a triumphal entrance on the world historical scene.

Some dozen years later, Narayan had joined the voluntary *bhoo dan* movement of the Gandhian Vinoba Bhave, and Asoka Mehta had left the Socialist party; Ba Swe and Kyaw Nien were in jail; and Sjahrir, having spent six years in prison, died shortly after his release in 1967. The Asian Socialist Conference itself was no more. Of the socialist governments, India had increasing economic and political trouble; Burma had come under a military dictatorship; Ceylon had swung back to a nonsocialist government; Indonesia was racked by an abortive Communist-inspired revolution in 1966, and by a military-led counterrevolution which massacred several hundred thousand communists and finally stripped Sukarno, the first president of the regime, of all his powers; Cambodia was perched precariously between East and West, struggling to maintain its independence during the Vietnam war; Singapore, after first joining Malaya to form the new state of Malaysia, broke away and remained a small independent enclave still proclaiming itself socialist. What had happened to these Asian socialist parties, and what had happened to the socialist governments?

One anomaly was that in these countries, which proclaimed themselves officially socialist, the Socialist parties were rarely in full control of the governments. In Burma, the Burmese Socialist party was for many years part of the ruling coalition of the Anti-Fascist People's Freedom League, and Ba Swe had at one time been premier of his country. In Indonesia, Sjahrir had been its first prime minister, in 1945, heading a coalition government. But the Burmese Socialist party was abolished in 1962, when General Ne Win seized power and proclaimed Burma a socialist state; and the Indonesian Socialist party, wiped out at the polls in 1955, was abolished by presidential decree in 1960, when Sukarno proclaimed *Resopim* (Revolution, Indonesian Socialism, and National Guidance) as the official ideology. Except for the period of the independence movements and the struggle against the colonial powers, and for a few short years after each country won its independence, the socialist parties of Asia have not played a major role in their nations, despite the official adherence of the governments to a socialist ideology. The regimes called themselves "socialist" but were not based on the socialist parties.

Unlike the socialist movements of the Middle East and Africa, which scarcely existed before World War II, the socialist parties of Asia had a long history of involvement with the international

socialist movement and socialist thought. Jayaprakash Narayan, who became a revolutionary Marxist at the University of Wisconsin in the late 1920s, founded the Bihar Socialist party in 1931, was acting general secretary of the Congress party during the civil disobedience movement in 1932, and founded the Congress Socialist party in 1933, first as a wing of the Congress party and after 1939 as an independent party. The party organ in the early 1930s, the *Congress Socialist*, was edited by Asoka Mehta. Like the socialist parties of Europe, the Congress Socialist party had its difficulties with the communists, who stigmatized it as being "social fascist" and a "left maneuver of the bourgeoisie." Its experiences with the communists led the Indian Socialist party in later years to take a strong anti-Soviet, antitotalitarian position. Sjahrir had been a leader of the Perhimpunan Indonesia (PI), the student association of Indonesians studying in Holland in the 1920s, and on his return to Indonesia in 1932, he was interned by the Dutch and kept in prison for ten years; upon his release, he organized and directed underground resistance against the Japanese.

The Asian socialist and student movements had long had "tutelary" relations with the European socialist parties, particularly since most of the countries were under imperial rule; and freedom for the colonies had been an important plank in the programs of the British Labour party, the Dutch Labor party, and others. Thus the leaders of the Asian socialist parties had gone through the doctrinal vicissitudes of the European socialist movements, and in most instances had themselves adopted democratic socialist positions. The weakness of these parties, particularly the Indonesian, was that they were primarily parties of intellectuals, with some following among the workers but no influence or base among the peasantry in societies that were overwhelmingly agrarian. Their orientation was largely urban, and as Marxists they regarded the industrialization of their countries as the normal path of development. Moreover, as parties of intellectuals, with only a small hold on the trade unions, they were peculiarly subject to the factionalism and divisiveness of intellectual groups who lack an anchorage. Individual socialists, such as Jayaprakash Narayan, Asoka Mehta, or Sutan Sjahrir, were at times enormously influential in their countries—but only as individuals and because of their individual talents, not as party leaders.

Most south Asian countries called themselves socialist even when the leading parties, such as the Congress in India or the Nationalist in Indo-

nesia, had no doctrinal faith, simply because they assumed that state direction of the economy and state planning were necessary for economic growth. And the difficulty for most of these countries was that, lacking any experience in planning, lacking the vital managerial talents, and, in many cases, lacking the needed resources, they wasted available resources and made mistakes that could not be absorbed by the economies. Many of the Asian countries, mesmerized by the idea of industrialization, assumed, in the early 1950s, that, following the Russian model, this meant a priority for heavy industry. Burma, for example, decided to build a steel mill, even though its main "natural resource" was the huge amount of gun scrap left behind by the invading Japanese and the defending British troops after World War II. Other expensive show-cases were also built, and precious capital and foreign exchange were wasted on large airports and other "visible" features put up to impress foreigners with the progress and modernity of the new country.

It would be a simplification, of course, to attribute the failures and setbacks primarily to defects in economic planning. As was indicated earlier, southeast Asia, more than almost any part of the world, is plagued by communal conflicts, so that the regimes have been torn by internal conflicts and by threatened and actual insurrection. Also, these countries have been caught in the crossfire of Great Power rivalries, particularly the demand of the United States for participation in SEATO (the Southeast Asia Treaty Organization) and the diplomatic and military pressure of the Chinese, who seek to extend their influence in southeast Asia. But apart from the real political and sociological problems, a crucial fact was that each of these countries plunged ahead on a course called socialist which not only was failing in practice but also was increasingly contradictory to the historic socialist ideals. The latter problem was foremost in the thinking of Jayaprakash Narayan, perhaps the outstanding figure of Asian socialism in the mid-twentieth century. Speaking at the second—and last—conference of the Asian socialist parties, in 1956, Narayan declared:

All our countries, except Japan, are backward economically and many are desperately poor. Naturally, therefore, our attention goes first of all to the problem of economic growth. There is nothing wrong in that, but the mischief starts when we begin measuring "socialist achievements" in terms of tons of steel and kilowatts of electricity. Economic growth, even rapid economic growth, is known to have occurred both under Capitalism and Fascism. Mere economic development is not a measure of socialism. I do not wish

to suggest that it is not the business of Socialists to see that more wealth is produced. What I wish to emphasize is the danger of equating socialism with economic development, and of sacrificing the values of socialism at the altar of that development. . . .

The main, if not the whole, emphasis is still being placed on the control and use of the power of the State. Everywhere socialists are organized in political parties which are attempting to seize power and hoping thereafter to build a new society. . . . But as I have said before the ideals of socialism remain far in the distance. The reason seems to me to be a wrong approach to these ideals. All of us agree that socialism is a way of life, an attitude of mind, a certain ethical behaviour. What is not so universally recognized is that such a way of life, attitude and behaviour cannot be imposed from above by dictates of the Government or by merely nationalizing industry and abolishing capitalism. Construction of a socialist society is fundamentally construction of a new type of human being . . . if human reconstruction is the key to socialist reconstruction, and if that is beyond the scope of the State, the emphasis in the socialist movement must change from political action to such work of reconstruction. (Quoted in Rose 1959, pp. 258-259)

Contemporary sociology and mature Marxism share a bias against utopian thought. What the Marxists called objective conditions, sociologists call structural constraints. The idea is the same: that the range of alternatives open to any society is limited by the starting point, the kind of resources, the degree of differentiation, and the like. Certain chosen paths impose certain imperatives: industrialization requires the creation of a technical class and a new kind of educational system; the increasing structural differentiation of a complex society requires a kind of social coordination different from a simple, top-down command system. Necessarily, such a perspective tends after a while to bring out the more limited choices of means of action, and in the process the ends are often forgotten or become ritualized. Socialism as a belief has been both a system of means and a system of ends; and throughout its history the means have invariably tended to diminish the ends.

In his youthful writings, Marx was most vividly concerned with the ends of human action. In the *Economic and Philosophic Manuscripts of 1844*, a halfway house in the development of his thought, Marx speculated on what the phase immediately following the socialist revolution might be. The negation of private property, he said, is not the aim of socialism, for what it does is to usher in a period of what he called raw or crude communism. Crude communism does not transcend private property but universalizes it; it does not overcome greed but generalizes it; it does not

abolish labor but extends it to all men. The aim of socialism, as a fully developed naturalism, as humanism, is to go beyond communism, beyond necessity, and therefore beyond history—which itself is a form of determinism—to a world which resolves the “strife between existence and essence, between objectification and self-confirmation . . . and between the individual and the species.” It is a world in which a human being no longer feels “divided” or alienated from what he believes his essence as a social being, as a person free to make his own future, can be (Marx 1844, pp. 104–114 in the 1919 edition).

This is the permanent utopian—and even religious—component of socialism, a quest, as ancient as man's fall from grace, to unify himself with an ultimate and to find a world of freedom. It remains a world beyond.

| IV. ADULT SOCIALIZATION      | Orville G. Brim, Jr. |

I  
PSYCHOLOGICAL ASPECTS

This discussion of the psychological aspects of socialization will focus on the *developmental* as-

pects of individual behavior which occur in or directly involve interaction with one or more persons, i.e., in a *social* context. Any interest in the differential effects of early experiences of the infant, of child-rearing practices, of peer group influences, in sum, of any of the factors which may shape the configuration of behaviors that is considered to be personality, directs us to the subject area of social development.

Interest in this area is probably as old as almost any other human concern and is portrayed throughout written history. It is documented in Biblical accounts, the works of philosophers, autobiographies, and treatises on child-rearing practices. These accounts have been written mainly on the basis of very limited evidence, usually little more than the author's own experiences. With the development of scientific methods for studying human behavior, investigators have increasingly turned their attention to exploring all aspects of social behavior and how it develops.

**Approaches.** Methods employed to study social development are to a great extent determined by the questions the investigator asks and include almost all the techniques which have ever been used in psychological research. The approaches range from experimental to correlational, longitudinal to cross-sectional, and comprise case studies, normative and descriptive studies, small sample comparisons within a limited social group, cross-cultural analyses of many primitive societies, interviews and questionnaires, direct observations, etc. An excellent discussion of the many different approaches is provided by John Anderson (1946). Currently, an increasing interest in methods and techniques per se parallels an increasing sophistication among investigators regarding the strengths and weaknesses of these methods and the modifications required when employing them with groups differing in important respects, such as age, social background, and race. In 1960 this interest in method was manifested when the Committee on Child Development of the National Academy of Sciences-National Research Council sponsored the publication of a collection of papers presenting what was considered the wisdom of expert investigators, gained over years of using these methods (Mussen 1960). This awareness of the need for careful assessment of the appropriateness of a technique to be applied to the questions, subjects, and inferences under investigation is a healthy sign. Publication of books and papers which focus on critical and frequent foibles in the use of certain approaches and methods stimulates concern with and creative use of old and new techniques.

### Historical perspective

**Geneticism and environmentalism.** One of the earliest controversies about the different factors involved in development was concerned with the relative impact on behavior of genetic endowment and environmental influences. This controversy led to heated arguments between most early researchers of social behavior. In the work of Binet (Binet & Simon 1905) on measuring intelligence, we see how taking a position on the environment-heredity issue can become associated with the goals and purposes of research without being a necessary assumption for it. As the attempts to develop a measure of intellectual abilities which would be comparable for different ages, would be stable for individuals over time, and would predict performance in school became increasingly successful, it was difficult not to acknowledge that what was measured was something mainly genetically endowed. And the relatively successful accomplishment of this goal led many to emphasize inherited characteristics over environmental influences. This position was clearly expressed by McDougall (1908), who, despite devoting much energy to the study of social development and being one of the first to use the phrase "social psychology," incorporated into his theory a long list of instincts. This preformationist position accorded little importance to the contribution of external factors to the development of many social behaviors, such as aggression, gregariousness, and even techniques of child rearing. Gesell (1946) was another important contributor to the genetic position, with his model of reciprocal interweaving of the processes of behavioral differentiation and integration. Although some recognition of the contribution of environmental influences was made in his discussions of learning, these external factors were clearly less important than the teleological processes determining individual development. This emphasis on inherited developmental tendencies is also seen in the writings of Piaget (1923). Piaget's schemata portray definite stages, or levels, of orderly progression, each stage occurring at a particular age, supporting the position of a genetically determined sequence in the developmental process. [See DEVELOPMENTAL PSYCHOLOGY, *article on A THEORY OF DEVELOPMENT*; GENETICS, *article on GENETICS AND BEHAVIOR*; INTELLIGENCE AND INTELLIGENCE TESTING; and the biographies of BINET and GESELL.]

A similar position, but with important differences, was earlier proposed by Baldwin (1897) to account for both the mental and social develop-

ment of children. He posited that children have an inclination, apparently innate, to imitate and that imitation occurs in specific stages. This position was further developed by G. H. Mead (1934), in his description of the process whereby one learns to assume the role of another person. Although Baldwin and Mead seemed to assume an innate tendency to imitate, their presentations make external events crucial in determining much of social behavior, since the child cannot imitate a model unless it is there to copy. [See IMITATION; and the biographies of BALDWIN and MEAD.]

**Psychoanalysis.** Interest in social development was further stimulated by Freud and the psychoanalytic theorists, whose position regarding the relative importance of innate and environmental influences is a mixed one. Although the basic driving forces of behavior are assumed to be inherited, many of the manifest forms of action are acquired through associations during interpersonal situations. The importance of these external events in the development of social behavior was especially recognized by Freud, who maintained that early familial influences could determine later personality characteristics. Freud was primarily interested in dynamic, complex motivations and how these dynamically interrelated forces account for the manifest social behavior of an individual. But in his early writing (1900) he addressed himself explicitly to the question of the basic mechanism accounting for these later complex associations. The key to this system, he proposed, is the reflex arc. Basic responses of personality are conditioned by early experiences. Clearly, then, the early experiences of each individual will be paramount in shaping his social development, according to this theory.

**Behaviorism and learning.** Although it was Pavlov (1927) who investigated and established the important variables involved in the acquisition of conditioned reflexes, he did not directly study social development. It was with Watson that conditioning became all-important in accounting for social behavior, as well as for almost all other behavior. Watson (1919) proposed that a person's actions are—aside from a limited number of innate reflexes—completely the product of conditioning experiences. With this theory the pendulum had swung to the far extreme, completely away from any instinctivistic assumptions. Watson demanded that only external events and directly observable behavior be considered in building a psychological theory. With his research on children and their neurotic fears, Watson seemed very interested in demonstrating to parents the practical applications

of his theory. Although the theory's influence on the field of social development declined after a decade, the attitude toward scientific investigations of behavior through experimental methods, based on operational definitions and measurements, has been lasting. In addition, the battle between the environmentalists and nativists no longer seemed to be of such importance. Future theorists would have to acknowledge the role of environmental events, no matter what assumptions or positions they took regarding genetic contributions to behavior. [See *LEARNING, article on CLASSICAL CONDITIONING; the biographies of PAVLOV and WATSON.*]

Much of the work by learning theorists, such as Thorndike, Guthrie, Tolman, and Hull, was very relevant to social development; but it was especially at Yale University's Institute of Human Relations that direct attention was devoted to research in this area. Hull (1943) provided the beginning of a systematic, mathematical account of the principles of learning, and this general theoretical approach was applied to the study of social development by Miller and Dollard (1941) and Mowrer (1950). Their work greatly stimulated research in this area, especially in the use of experimental methods. The creative use of this theoretical orientation for explanation was demonstrated by Whiting (1941) in his interpretation of the socialization processes involved in the development of a child in a primitive culture. Studies by Sears (Sears et al. 1953) of antecedent-consequent relations in parent-child behavior have given great impetus to the study of the impact of child-rearing practices on personality development. [See *the biographies of GUTHRIE; HULL; THORNDIKE; TOLMAN.*]

**Field theory.** Kurt Lewin stimulated others to direct their attention to social development, especially where such behavior occurred in different environmental settings. Although his own work dealing with the development of social behavior was not extensive, the work of those influenced by his teaching and writing has been. (See, for example, Barker et al. 1943.) The conceptual scheme which he proposed, called field theory, emphasized the gestalt principle of considering the total situation, that is, all the factors in the environment which might affect behavior, as well as the personality characteristics of the individual. This orientation has stimulated interest in the ecological approach of studying the persisting conditions in the environment which significantly affect social development. [See *FIELD THEORY; GESTALT THEORY; and the biography of LEWIN.*]

**Operant conditioning.** One impetus for a recent surge in experimental orientation comes from the

work on operant conditioning by Skinner. Although his own research dealt mainly with animals, he has discussed the application of his approach to the development of complex human behavior (1953) and even the establishment of a utopian culture (1948). His methodological prescriptions for an experimental analysis of behavior have stimulated the application of a different approach to many areas of social development previously studied mainly by indirect routes involving circuitous interpretations. [See *LEARNING, articles on INSTRUMENTAL LEARNING and REINFORCEMENT; UTOPIANISM, article on THE DESIGN OF EXPERIMENTAL COMMUNITIES.*]

Although investigators differ in their theoretical orientations, their use of this experimental, behavioral approach, which to some degree involves a consensus about terms to use in describing research, has brought many diverse questions of social behavior under similar methodological inquiry.

### Areas of research

**Characteristics of the child.** Until the 1960s most research assessed the influence of external events on the infant as if it were a one-way process. Research in the 1960s, however, shows that neonates have different sensitivities and reactions to stimulation. Some of these differences have been related to constitutional characteristics of the infant and to the conditions of birth, such as amount of anesthesia and difficulties of delivery. Research now being conducted on infant-mother relations considers the interaction between the child and mother—both the degree to which the child influences the mother's behavior and the degree to which the mother influences the child. For example, the findings that children difficult to toilet train are insensitive to unpleasant odors and that children very sensitive to being wet are easy to night-train indicate the potential interaction between important socialization processes and the child's reactivity to relevant stimuli.

**Sex.** Studies of social development must consider the sex of the child, since the varied components of appropriate sex-role identity may be differentially influenced by many factors from the first days of life. There is evidence that some differences in early behavior are related to constitutional sex differences (Bell 1960). Among infant monkeys, for example, males actively engage in aggressive play, whereas the females tend to stay on the fringe of such activity (Harlow & Harlow 1962). In cross-cultural studies such sex differences in aggressive play also have been found to

hold for children. These sex-related behavioral proclivities are probably reinforced by society, since they conform to sex-role expectations. Parents may, even without awareness, encourage certain behaviors in their sons and other behaviors in their daughters from birth. If this speculation is justified, current and future studies of early parental treatment, where very subtle aspects of rearing practices are measured, should show differential handling for the sexes, beginning with the neonate. [See *INDIVIDUAL DIFFERENCES*, article on *SEX DIFFERENCES*.]

*Ordinal position.* Ordinal position has been related to important social behavior, such as the development of affiliative motivation. Studies (e.g., Schachter 1959) indicate that under certain kinds of stress first-borns tend to want to be with others more than do persons who were born in a later ordinal position. It is possible that the amount of attention paid to the children changes, with less attention given to individual children as the family increases. It seems likely, too, that the parents' behavior changes, because of their own differential experiences with children: as subsequent children arrive, the parents have more confidence in themselves and less anxiety about things that happen to the child. The greatest difference in treatment would most likely be between the first child and the others, but probably there are differences in handling each child. The consistency of differential treatment across families needs to be studied to determine the conditions that give rise to the effects associated with ordinal position. [See *INDIVIDUAL PSYCHOLOGY*; the biography of *ADLER*.]

*Age and maturation.* The age and maturational level of a child determine whether the occurrence of a particular event will have any salient effect on him and how permanent such an effect might be. The importance of age in relation to certain environmental conditions or learning situations will be evident throughout the following discussion.

*Early environment.* Studies of the effects of institutions on children indicate that the quality of stimulation provided by the environment may have critical consequences for the child. Research in maternal deprivation suggests that there are many important differences in the extent and quality of mother-child separation. Some immediate, measurable effects of maternal separation on the child's behavior have been demonstrated, but there is little evidence of any long-term consequences if the separation is not followed by conditions that frequently compound the event. When separation is followed by institutionalization, however, the evidence suggests that serious personality

impairment may result: deficits in motor, language, and social development. Such undesirable effects are not necessarily the result of being placed in the institution per se. Differences in the amount of stimulation given children in different institutions are associated with differential degrees of deleterious effects. Unfortunately, many of these institutions provide rather impoverished environments for infants and young children. Therefore, the immediate conditions experienced in the institution should be considered the major cause of deficits, rather than institutionalization itself. It may then be discovered that these conditions and experiences have the same effect on children never separated from their parents. The institution may tend to impose on the child a schedule which does not permit him to learn important social responses or perceive and react to caretakers and other persons in the way most children do. Researchers (e.g., Lovaas et al. 1965) are investigating ways of stimulating autistic and socially unresponsive children who have been markedly affected by such conditions to react to other persons as important stimuli in their environment. This work will attempt to modify social apathy and indiscriminate response to caretakers among these children and increase their tendency to imitate others. Work with animals that is analogous to therapeutic procedures (Schoenfeld 1950) suggests that even though the retarded or deviant behavior may be desirably modified, the person may still have a tendency to react to any future experiences of a similar nature in a dramatic fashion, responding abnormally under certain stressful conditions. [See *INFANCY*, article on *THE EFFECTS OF EARLY EXPERIENCE*.]

*Critical periods.* The question whether there is a "critical period" for institutional deprivation experiences is unsettled. There is some suggestion that the age at which institutionalization occurs has different effects: retardation is associated with early commitment, whereas children eventually diagnosed as schizophrenic tend to have been institutionalized at a later age. There is some evidence that children who have a tonsillectomy when they are between three months and three years of age are more affected than children whose tonsillectomies occur when they are either younger or older. Even within this period, the effects are lessened by preparing the child before the operation and by having a familiar adult, usually his mother, with him as much as possible during his stay in the hospital. Since some individuals who experienced severe early childhood traumata due to separation from parents are not notably disturbed in

later years, it would seem that the deprivation must be of a certain kind or quality or extend over a certain period to have any lasting effect.

*Father models and initiations.* Most of the research on separation and early deprivation focuses on the mother-child relationship and does not deal as much with the role of the father. This tendency to ignore the father's influence on the child has been true of much of the research in child development. There is support, from cross-cultural and experimental studies, for the hypothesis that a child will imitate and identify with a person who controls his important resources. This theory suggests that the relationships between parents and other persons in the child's awareness and their differential control of resources are important variables in his social development. Not only should child-rearing techniques be investigated, but research ought to consider by whom and under what conditions they are exercised.

There is evidence that a weak or absent father distorts a boy's sex identity so that he tends to be effeminate or compensatorily overmasculine. Cross-cultural studies indicate that the custom of the initiation ceremony serves to fix masculine identity in boys in societies where the father is not in the household during the first two years of the child's life (Burton & Whiting 1961). Similar conditions appear to exist in the lower-class subculture of the United States, especially in areas with delinquent gangs. Initiation rites into these gangs have characteristics similar to those of the initiation ceremonies of primitive societies, except that the rules for the boys in the primitive societies are socially desirable whereas the rules for the lower-class gang are often socially unacceptable to the society at large. Research is now needed to test whether or not any of the important elements of the initiation rites of primitive societies might function in a desirable manner for boys in our culture with the early experience of father absence or the presence of a poor father model. Furthermore, one should not look just at the undesirable side of these conditions; one also ought to consider what socially desirable behaviors—such as artistic, literary, or athletic pursuits—might result from early deprivation experiences. In the area of parental deprivation, the relationship between the absence of a male model in the home and the development of girls and the differential effects on boys and girls of maternal separation also need investigation (L. Yarrow's 1961 review contains a fuller discussion of many of these issues and studies).

*Deprivation and stimulation.* A program of comparative research stemming from the effects of

"gentling" animals to be used for experimental work shows that permanent behavioral and physiological effects are caused by different experiences during infancy. These effects are directly related to social development; animals (mainly rats) so handled tend to be less emotional, can solve certain types of problems better, are less timid, and are constitutionally more robust and socially more dominant than nongentled animals. Not as much research has been done in assessing effects of extra stimulation on children. Some early work has indicated that the later performance of children given special training for certain tasks is not very different from the performance of children who were not trained until they were more mature and could learn the tasks with a small amount of effort. Recent work does show that differential handling of infants affects their physical development: certain types of handling are associated with earlier sitting up and walking. There are also data suggesting that gentling affects human infants as well as animals, i.e., extra holding, rocking, and cuddling produces more placid and more contented babies, compared with those stimulated only for essential caretaking.

The research with animals also shows that early stimulation directly affects the growth of their endocrine system. One cross-cultural study (Landa & Whiting 1964) shows that infancy stimulation in humans has an effect on height similar to that of infancy stimulation in animals. In societies with early stressful handling (baths in water of extreme temperature, massaging, piercing of skin) the average male height is greater than in societies without such customs, even when many factors known to affect growth—such as diet, sunshine, genetics, and geographical region—are controlled. These findings should stimulate additional research into the potentially beneficial effects of certain types of infancy stress in humans. The position that any stressful stimulation during infancy should be avoided would be challenged by this research. [See STRESS.]

One sees from the research on infancy that too little stimulation is deleterious and that an extra amount of regular or "normal" stimulation promotes desirable behavior; now there is even the possibility that stressful stimulation may cause some desired consequences.

*Child-rearing practices.* Much of the research on child-rearing practices has been based on interviews and questionnaires. Most of this information has been organized along two or three conceptual dimensions: love-hostility, control-autonomy, and, possibly, calm detachment-anxious emotional in-

volverment (Becker 1964). While this is considered a useful conceptual framework for organizing research material, such two-dimensional or three-dimensional models are not meant to be any "truer" representation of the way parents interact with their children than are other models. Furthermore, these dimensions must be combined in just the right amounts, to describe what an actual parent is like. It is revealing that these data, coming from measures of verbal behavior, have a factor structure which seems very similar to the structure consistently found in studies of the underlying meaning in language: evaluation (good-bad), potency (strong-weak), and activity (fast-slow). The order or strength of the factors also is the same: good-bad or love-hostility tends to be the first factor; strong-weak or control-autonomy, the second factor; and fast-slow or high involvement-calm detachment, the third.

*Disciplinary procedures.* For general discussion, disciplinary techniques can be placed along a positive-negative continuum which appears to reflect an attitude shared by most middle-class American parents (and by research scientists). The positive techniques include rewarding, praising, and reasoning—practices considered to be psychological and love oriented and which in some ways reflect a child-centered attitude on the part of the parent. The negative methods, such as physical punishment, yelling and scolding, derogating, and threatening, reflect a more egocentric parent, in that they appear to express more of the parent's frustration over the child's behavior. Since studies in which data are obtained in interviews or questionnaires also indicate that positive disciplinary techniques are used by parents who are positive in other ways, such as providing a warm home environment and being interested in the happiness of their children and in developing their potential talents, it is difficult to winnow out just what important factors are involved in these research findings. In general, however, the positive methods of child-rearing are related to the following characteristics in the child: low aggression, low undesirable dependency, high sociability, and a high level of conscience development and of moral judgment, as reflected in a feeling of responsibility for his actions, the experiencing of guilt for deviations from prescribed standards, and the confessing of such deviations. Negative techniques are associated with the undesirable aspects of these behaviors (Becker 1964 provides a general review of this research).

These findings are frequently complicated, in that the relationships may hold only for boys or only for girls. For example, high maternal warmth

and nurturance has been associated with high conscience and leadership in boys but with low conscience and dependency in girls. Possibly, since any technique would be used in a much broader context of shaping the child in the appropriate sex role, with all the concomitant aspects of this complex concept, such as aggression, dependency, independence, differential physical and cognitive skills, demonstration of affection and other emotions, etc., the same child-rearing technique could produce quite different behavior in boys and girls. Still, it is difficult to accept, without further investigation, the idea that the same child-rearing practice by the same parent should produce opposite effects in a son and in a daughter. The evidence must be considered in light of the differential perceptions usually found for children and parents. Boys are seen as more aggressive, independent, and difficult to train than girls. Mother and father perceptions also conform to sex-role stereotypes. Mothers, as compared with fathers, are seen as more nurturant and loving and as less strict, using less physical punishment but more psychological types of discipline, and are less fear-arousing than the father. Since the same-sex parent is seen as more restrictive and frustrating than the opposite-sex parent, there are interactions in these perceptions. In addition, the father's use of physical punishment is especially frequent with boys, and the mother's use of psychological control is rated as being more appropriate for girls than for boys. These differential perceptions may account for some of the differences in the consequences of the same parent-child relationship. Many of these relationships probably reveal more about beliefs or values of the respondent (mother, father, teacher, or child) than they reflect the actual methods or personal characteristics considered important in child rearing. The contaminated research design (all data from the same respondent) used in most of these studies raises questions about the validity of the measures and the relationships between them. Expectations of investigators and types of bias within respondents have been shown to effect just such findings as those in the child-rearing research. Investigations of the degree of correspondence between measures obtained at the time child-rearing events occurred and retrospective accounts of these same events show little correlation (M. Yarrow et al. 1964). The number of significant correlations between measures of rearing techniques obtained through direct observations of parent-child interactions and measures of these same techniques obtained through interview ratings or questionnaires is no greater than chance (Zunich 1962;

Brody 1965). These data give us pause when we consider interpretations of findings in child-rearing studies. There is a trend, in this research, for investigators to cross-verify results based on indirect methods with the results of more direct measures, a trend which seems necessary to clarify some of the theoretically conflicting interpretations proposed by different researchers.

There are serious difficulties in demonstrating the relationships of child-rearing practices with later behavior, because of the many intervening events which may lessen the evidence of some direct effect. On the other hand, behavior learned by a small child may not manifest itself until a much later time, when it is appropriate. Certain questions, therefore, can be answered only through longitudinal studies, even though they are difficult and costly to execute.

**Psychoanalytic propositions.** Psychoanalytic theory stimulated interest in the effects of early socialization processes on social and personality development.

**Weaning and oral behaviors.** Freud termed the first period of development the oral stage and attributed many enduring consequences to events surrounding oral stimulation and frustration, especially the feeding process. In spite of a great deal of research dealing with types of nursing (breast or bottle, demand or scheduled) and weaning practices, there is little consistent evidence of permanent personality characteristics related to these feeding experiences. There seem to be no differential personality consequences between breast and bottle feeding; the important variable appears to be how the mother feels about it. The amount of upset associated with weaning has been shown to increase with the length of time the child nurses, up to about 12 months, at which time it begins to decrease; in other words, there is a curvilinear relationship between amount of upset and length of nursing. Cross-cultural research suggests that the amount of upset is related to adult oral anxiety, measured by the extent of attributing illness to something one has eaten. Perhaps of greater interest to parents in our society is the fact that thumbsucking has also been related to upset over weaning. Nonnutritive sucking, however, is not necessarily an index of anxiety. Research indicates that it may just as well be associated with a strongly reinforced habit as with the amount of disturbance and frustration involved in feeding and weaning. These data suggest that if only a positive experience has been associated with sucking, the response is modifiable by making some incom-

patible response more rewarding. However, thumb-sucking seems to be self-rewarding, so it will not just stop by itself—at least not for a very long time. Punishing it appears to make it more resistant to elimination. For the present, one recommendation to parents who wish to stop their child from thumbsucking is to give him a pacifier. This seems to be quickly forgotten by the child when it is too much trouble for him to find or when something interesting engages his attention. The response is then broken up in the natural course of events and disappears.

**Toilet training.** The many studies of toilet training have also tended to yield generally inconsistent and insignificant results. The traits considered characteristic of the “anal” personality, i.e., parsimony, obstinacy, orderliness, have been found to occur together in people, but the indications are that these behaviors are more likely due to direct training than to the indirect effects of toilet training. This suggests that the learning conditions established by the mother and her attitudes about her child, which may determine her toilet-training regimen, have lasting effects on social development.

**Aggression and dependency.** Two of the most thoroughly investigated areas of social development are aggression and dependency. These domains have been studied using many different methods and with both humans and animals as subjects. In general, physical punishment by parents is related to physical aggression in the child. There is evidence of limiting conditions for the overt expression of aggression, especially for girls. When fantasy and direct observations are used as measures, covert aggression is directly related to the extent of parental use of physical punishment, but overt aggression is curvilinearly related (Sears et al. 1953). Where there is no physical punishment, the child shows little aggression. As parental use of physical punishment increases, so does the child's aggressive behavior—up to a certain point. It seems that at some level of punishment overt aggressive behavior is inhibited, but covert aggression—as expressed in fantasy—is not. This information indicates that the more aggressive the parents are toward the child, the more aggression will be produced in the child's motivational system, even though overt aggression may be discouraged when the punishment is severe enough. The implication is that there might be some conditions under which this repressed hostility would become overt. Direct support for this conclusion comes from experimental studies which show that a child will imitate the aggressive behavior of a model

when the opportunity presents itself and the context indicates that no punishment for such aggression will occur (Bandura & Walters 1963). Such findings are supported by cross-cultural research which shows that societies rated high on use of painful child-rearing customs (rough handling and physical punishment) tend to have aggressive rather than benevolent gods. Other studies demonstrate that aggression can be produced in children through permissiveness toward and direct rewarding of aggressive behavior.

For dependency, the evidence again is that it may be produced through direct reinforcement. In addition, the combination of rewarding dependency when the child is young and then frustrating or punishing such behavior after it becomes part of his behavior pattern seems to produce dependency of a more rigid and persistent nature. If no punishment is associated with dependency behavior, it seems that not reinforcing it any longer will extinguish it. In light of the findings of investigations of both aggression and dependency, a reasonable hypothesis appears to be that behavior which is rewarded and encouraged in the early years and then punished when the child is older will be difficult to control and stop. Current evidence suggests that an effective procedure would be to stop rewarding the behavior the parent wants to eliminate and reward some incompatible behavior instead.

**Modifying behavior.** Research in nursery school settings has revealed that social dominance, timidity, aggression, socially desirable interactions with peers, and somewhat aberrant idiosyncratic behavior, such as crawling or walking on hands and feet rather than upright, can be modified through applying social-learning paradigms, mostly some adaptation of operant conditioning in the natural setting (Scott et al. 1967). The basic design of these experiments is to have a teacher or other adult give affectionate attention immediately following the desired behavior and not respond in any way to the undesired acts. Such studies usually demonstrate that the less-desired behavior was being maintained through the teacher's paying attention to the child (often by scolding) only when he was doing what she did not want him to do. By contrast, the teacher tends to ignore him when he behaves well. Rarely have these studies investigated the combination of positive and negative reinforcement for desired and undesired behavior, respectively. Since there is evidence from learning experiments that when the two responses are mutually exclusive such differential rewarding and punishing is the most efficient teaching paradigm,

it will be important to know how such contingencies work in a natural, everyday teaching situation. The hypothesis stated above for aggression and dependency implies that once behavior has become part of the child's repertory of responding, the introduction of punishment, while it may inhibit the behavior temporarily, will actually make it more resistant to modification. However, if there is a mutually exclusive type of behavior readily available for the parents to reward, a combination of disapproval of the undesired activity and approval of the acceptable behavior may be more effective than trying to modify the behavior through approval alone. [See *LEARNING, especially the articles on INSTRUMENTAL LEARNING and REINFORCEMENT.*]

**Labeling.** There is experimental evidence that clear labeling of behavior helps a child discriminate in one situation and then transfer his learning to a new situation. This finding suggests that parents and teachers will be more successful in developing certain desired social behavior in their children by clearly labeling the behavior they are rewarding and punishing. This interpretation implies that the more they provide the child with cognitive support for their approval and disapproval, the more the child will understand how he should act in a quite different place but where the abstract aspect of the situation is the same.

**Consistency.** The desirability of consistency in child rearing is often stated. However, there are many kinds of consistency possible, ranging from the evaluation of certain behavior as always good or always bad to the unvarying use of certain techniques for rewarding or punishing. Most research on consistency has addressed itself to consistency of the former type. Inconsistent or capricious discipline is associated with socially undesirable behavior, as is apparent from studies of delinquents and their parents. There is evidence which suggests that some ways of being inconsistent would produce desired results. First, if the parents always use the same kind of reward (or punishment), the child might become satiated with it (or adapt to it) and its power to reinforce would be attenuated. This suggests that to maintain effectiveness, rewards and punishments for the same type of behavior should be varied. Studies also show that once behavior is well established, making rewards or punishments unpredictable for the child will maintain the behavior in the absence of the parent better than if the parent is consistent in rewarding every time the child acts well or in punishing every time he is bad. The important distinction here is

that a type of behavior, when it is reinforced, is either always rewarded or always punished, in contrast to the undesirable kind of inconsistency, where the same behavior is sometimes rewarded and sometimes punished.

**Peer-group influences.** The first peer group for many children consists of their siblings. The sex of these siblings is important to the child's social development since older sibs may have much influence over him, both directly, through rewarding and punishing his behavior, and more indirectly, through providing a model. These experiences would be expected to affect his later social relations (Koch 1960). There is evidence that a later preference for same-sex or opposite-sex playmates is related to whether the child has had opposite-sex sibs or not, relatively greater preference for opposite-sex playmates being associated with having opposite-sex sibs (Koch 1957).

Studies have assessed the effects of nursery school and kindergarten attendance on social development, based on the assumption that such effects stem from the child's association with other children his age. The results are inconsistent: some show positive associations with desirable social development, and others show no relationship or even show some indication, in the investigator's opinion, that the child in nursery school may be habituated in his behavior too early. To a great extent the variability of results seems due to differences in the kinds of measures and behaviors employed in these studies. At this time there seems to be little that can clearly be stated about empirical results or that would lead us to even a tentative conclusion about the differential effect of preschool attendance *per se* on a child's social development. Differences between various nursery school settings do have differential effects on the child's social behavior, but investigations to determine the important variables distinguishing the settings still need to be made. Some studies clearly show that social behavior of individual children, as well as group differences, are modified by certain training regimes and specific procedures. Ascendancy and submission, social participation, leadership, and positive and negative social interaction have been the behaviors modified in the direction considered desirable.

Peer influences on social behavior have been shown to affect aggression, honesty, expressed values, leadership, participation in diverse extra-curricular activities, friendship choices, and identity with a group and its activities. These differences in behavior have been related to whether the

child was a member of a particular clique, club, classroom, school, or social class. For some of these associations it is difficult to determine how much to attribute to peer influences and how much to more basic factors, such as family influences, which would determine the child's assignment to these different social units. However, it seems clear that the peer group does influence the social behavior of the child, even if such influence is only to reinforce behavior which was already a part of the child's repertory. Interesting demonstrations of peer influences on social development come from studies of the *kibbutzim* and of Soviet methods of character training. Analyses of these peer settings indicate that the peer group does act as a powerful socializing agent in rewarding and censuring and successfully shaping behavior of its members in conformity with the group's standards. The evidence available for the Soviet methods of education comes mainly from analyses of their written works, with some support coming from interviews with teachers and a limited amount of direct observation in the schools (Bronfenbrenner 1962). More extended research of socialization has been possible in the *kibbutzim* of Israel. Direct observations in the nursery indicate that the peer group is important in developing socially desirable habits of eating, toileting, sex, independence, and aggression (Faigin 1958).

The sex and age of the child are important attributes in determining what peer grouping he becomes a member of and how the peer group acts toward him. Cross-cultural studies indicate that from the earliest years the sexes are treated differently by their parents. Other studies indicate that the teaching of behaviors appropriate to the different sex roles, which is begun in the home, is reinforced by the peer groups. Sex seems to be the major determinant in early peer grouping, where the members engage with a vengeance in sex-typed play and eschew behavior considered to be characteristic of the opposite sex. With increasing age, individual friendships become stronger, the role of the individual in the group becomes more distinctive, organized social activity increases, and the individual's identity with the group and the degree to which he is controlled by the group's sanctions increases. Even for groups formed for just a short time, there is evidence that reputations and expectations of an individual's behavior are quickly formed and are quite stable. Such social perceptions by the peer group appear to be strong determinants in shaping the member's behavior to conform to his reputation and the expectations the

others have for him (Campbell's 1964 review provides fuller coverage of this topic).

**Other influences.** Since the average American child spends much time watching television and motion pictures, the importance of these media for teaching values and different kinds of behavior is obvious. A program of research in social learning by Bandura and Walters (1963) shows that children will imitate an aggressive model in a motion picture. Watching aggression in a movie also elicits preference for and participation in aggressive play. For adults there is some evidence that, when an individual is already aggressively aroused, watching an aggressive movie acts as a catharsis. For children, however, far from acting as a fantasy reduction of aggressive impulses, the viewing acts to arouse aggression in them. These studies indicate that aggression is more easily aroused and elicited in children than are other forms of behavior. There is some indication that adolescents who watch television programs depicting many stresses and strains of adult life are likely to be more anxious and dependent on their families than are children who do not watch such programs. Television viewing has been associated with a tendency to stereotype nationalities and at the same time with a tendency not to ascribe value judgments to minorities. The evidence suggests that the mass media may have both very desirable and undesirable influences on social development. The effects of viewing appear to be found mainly when the behavior learned is reinforced in the home or is not dissonant with the home values. Still, the implication is that parents would do well to exert some supervision over the viewing choices of their children.

**Reading material.** Little evidence of the effects of reading material on behavior is available. Studies have shown that the reading of an inordinate number of comic books, especially those with highly aggressive content, may be a symptom of emotional problems in a child and is more characteristic of delinquent children than nondelinquents. But the causal relationship is not clear, since the disturbed child may turn to the fantasy material because of his anxieties. Content analyses of recommended children's literature indicate rather consistent portrayal of certain roles having certain behavioral traits. This probably reinforces what the child is learning in the home, school, and peer groups about these roles. What the child reads may, nevertheless, teach him certain attitudes, values, and behaviors, which may later be manifested as overt behavior in appropriate situations. But at this time

there seems to be no clear evidence in support of this hypothesis.

### Trends

Several main currents in the flow of research in social development may be noted. One of these, which has a well-established tradition and has always been an integral part of this area of investigation, is the application of learning principles from the experimental laboratory to the more complex areas of human behavior. This paradigm has been especially prominent in recent research investigating some of the important parameters involved in the development of social behavior. The way of thinking about stimuli, responses, reinforcements, and the many other factors found important in experimental studies has been employed both in the design and in the conceptualization of studies of social behavior in nonexperimental settings, and this trend is increasing. This stamp has been felt in no small way in the tightening up of definitions of the behavior and other variables under study. The influence seems to be most apparent in the following kinds of research: (1) observational studies, where data are obtained in a sequential manner in order to ascertain the potential effects of immediate events on behavior; (2) applied uses in therapy and in the modification of behavior of institutionalized persons; and (3) the creative use of experimental designs in natural settings, where the changes in behavior produced by the experimenter's control of the environment are investigated.

Another dominant trend is in the self-conscious awareness of methods and measuring techniques. There are signs of uneasiness about the labels that have been applied to certain measures which have not been carefully tied to actual behavior. There is increasing use of research designs to assess the correspondence between indirect and direct measures of attitudes and beliefs and their overt behavioral manifestations. The indications are that information from all these levels will provide a fuller understanding of the processes involved in behavior and its development. New techniques are being devised to record and analyze sequential events, in order to assess the effects of different environmental contingencies in determining actions. Obtaining such data in turn demands the development of new kinds of multivariate analytical models, especially for analyzing interaction sequences in a setting such as the home or school.

Another important trend stems from studies of the newborn. These studies have forced researchers

to consider possible genetic factors involved in social development. Emphasis is placed on studying the mother-infant relationship as a truly dyadic one, where the infant is shaping the mother's behavior as well as being affected by her. The concept of "critical periods" has been given special consideration in this area of research. The question of whether an experience has differential effects depending on the maturational age of the child is now being extended from studies of the infancy period to studies involving later ages. ## II

## ANTHROPOLOGICAL ASPECTS

"Socialization" gained currency in the 1930s as a term denoting the process by which culture is transmitted from one generation to the next. Dollard described the process as "an account of how a new person is added to the group and becomes an adult capable of meeting the traditional expectations of his society for a person of his sex and age" (1935, chapter 1). Although a review article by Irvin Child entitled "Socialization" (1954) signaled its formal acceptance, persons doing research on this process have never been too happy with the term—in part because of its ambiguous connotations and in part because it suggests that the concept is limited to the learning of social roles. This implied exclusion of the transmission of beliefs, values, and other cognitive aspects of culture led Kluckhohn (1939) to suggest "culturalization" and Herskovits (1948) to propose "enculturation" as alternative terms. Although these terms, especially the latter, have much to recommend them, they have not been widely used. Nor has "socialization" been universally accepted. "Child rearing" seems to be gaining some favor as an alternative (Sears et al. 1957; B. Whiting 1963), but it also fails to suggest cultural transmission.

## Psychoanalytic and cultural approaches

The writings of Freud turned the attention of anthropologists to the study of socialization. Although culture is by definition (Tylor 1871) learned anew by each generation, the study of this process was almost entirely neglected by anthropologists until after 1925. Up to this time, American anthropologists were primarily concerned with the history of cultures and with describing how traits were diffused or borrowed. For example, in their ethnographies a description of a cradle board detailed sufficiently so that it could be identified as either a "Plains type" or a "Plateau type" was often

the only material bearing in any way on infancy or childhood. In Europe and England, where evolutionary theories were in vogue, there was even less concern with this topic.

The early writings of Freud were little noticed by anthropologists, but when *Totem and Taboo* appeared in 1913, this invasion of the ethnological domain could not be ignored by them. For the most part, the initial response of anthropologists was negative. Kroeber (1920) wrote a critical review of the work in the *American Anthropologist*, and Malinowski (1927), in an attack upon Freudian theory, argued that the Oedipus complex did not occur in the Trobriand Islands. It was Edward Sapir who anticipated the view of psychoanalytic theory that was to be taken by many anthropologists:

Those who are profoundly convinced of the epoch-making importance of the psychological mechanisms revealed by Freud and, even more, of the extraordinary suggestiveness of numerous lines of inquiry opened up by psychoanalysis, without, at the same time, being blind to criticisms that need to be made of certain psychoanalytic theory, can only hope and pray that this not altogether healthy overpopularity of the subject prove no hindrance to the study of the perplexing problems with which the Freudian psychology bristles. ([1917] 1949, p. 522)

Margaret Mead, setting sail for Samoa in 1925, was the first anthropologist to engage in field work with the avowed intention of studying an aspect of socialization. In this first study, she was not strongly influenced by psychoanalytic theory. In her report on the life of adolescent girls (1928) she did not talk of Oedipal complexes or oral fixations but rather about the everyday life of these girls, paying particular attention to the ways in which their lives contrasted with those of American girls of the same age. Her description of growing up in New Guinea (1930) was also more anthropological than psychoanalytic in its conception, but her later study of three contrasting cultures in New Guinea (1935) clearly showed Freudian influence.

During this early period two psychoanalysts, Géza Róheim and Erik Erikson, did field work in non-Western societies; the former worked mainly in Australia and Melanesia (Normanby Island), and the latter studied the American Indians (Sioux and Yurok). Both of them reported child-rearing practices and interpreted some of the rituals, values, and customs as the consequence of unconscious conflicts engendered by these practices. Róheim was so arbitrary and dogmatic in his interpretations that he antagonized many anthropologists and gave the study of socialization a bad

name among the more conservative members of the profession. Erikson's interpretations were, by contrast, sensitive, illuminating, and nondogmatic—a fact which did much to counteract the influence of Róheim (see Erikson 1950).

In 1932–1933 Edward Sapir and John Dollard gave a joint seminar on culture and personality at Yale University. Dollard, a sociologist, had just returned from Germany, where he had received psychoanalytic training. The combination of the cultural and psychoanalytic approaches for the study of personality development was clearly expressed by Dollard soon after this in his *Criteria for the Life History* (1935). Partly as a consequence of this seminar, a number of life histories of preliterate men and women were published (see Dyk 1938; Ford 1941; Talayesva 1942).

A few years later Abram Kardiner, a psychoanalyst, and Ralph Linton, an anthropologist, instituted another seminar on personality development, held this time at Columbia University, which resulted in the publication of two important volumes: *The Individual and His Society* (Kardiner 1939) and *The Psychological Frontiers of Society* (Kardiner 1945). These consisted of case studies of a number of societies whose projective systems were interpreted in the light of their "basic disciplines," for example, weaning, toilet training, and the control of sex, dependence, and aggression. The cultural material was supplied by an anthropologist with a firsthand knowledge of the case; in most instances the field work had been done prior to the seminar. Cora DuBois' work on the Alorese, reported both in the second volume and in a separate monograph (1944), was a landmark in the study of socialization from the combined viewpoints of psychoanalysis and cultural anthropology.

The influence of psychoanalytic thinking upon anthropologists that occurred mainly in the decade 1925–1935 resulted in a dramatic change in ethnographic research. Most general ethnographies written after 1930 included descriptions of infancy and childhood. Furthermore, field studies explicitly focusing on the socialization process were undertaken. Child-rearing practices were even used to interpret the "national character" of modern nations [see NATIONAL CHARACTER].

### Learning theory and socialization studies

In the mid-1930s, learning theory was added as a third component in the study of socialization. This came about as a consequence of a seminar at the Institute of Human Relations at Yale University. Among the participants in this group were John Dollard and Earl Zinn, representing the psy-

choanalytic viewpoint; C. S. Ford, B. Malinowski, G. P. Murdock, and John W. M. Whiting, representing anthropology; and Leonard Doob, Carl Hovland, Clark Hull, O. Hobart Mowrer, Neal Miller, and Robert Sears, representing learning and behavior theory.

Since both the psychoanalytic and the cultural approaches imply learning, the early studies of socialization had an implicit and usually common-sense theory of learning which seemed to serve the purpose well enough at the ethnographic level. Thus Mead described an aspect of Samoan education as follows:

From birth until the age of four or five a child's education is exceedingly simple. They must be housebroken, a matter made more difficult by an habitual indifference to the activities of very small children. They must learn to sit or crawl within the house and never to stand upright unless it is absolutely necessary; never to address an adult in a standing position; to stay out of the sun; not to tangle the strands of the weaver; not to scatter the cut-up cocoanut which is spread out to dry; to keep their scant loin cloths at least nominally fastened to their persons; to treat fire and knives with proper caution; not to touch the kava bowl, or the kava cup, and, if their father is a chief, not to crawl on his bed-place when he is by. These are really simply a series of avoidances, enforced by occasional cuffs and a deal of exasperated shouting and ineffectual conversation. (1928, pp. 22–23)

The attempt by John W. M. Whiting (1941) to apply a more formal version of learning theory to the socialization process of the Kwoma of New Guinea was, as Gladwin comments, "so literal that it was almost a tour de force. The exercise has therefore not been repeated" (1961, p. 153). Certainly the Kwoma data were in no sense the test of a theory, but they did provide a vehicle for presenting a view of certain aspects of the socialization process. In this study the role of the socializing agent was stressed, as indicated by the following quotation:

A Kwoma child learns but a small part of his cultural habits by free trial and error, that is, without some member of his society guiding and directing him. Were he to do so, he would learn those habits which were most rewarding to him and to him alone. This, however, is not what actually happens. He is forced to learn, not the habits which might be most rewarding to him alone, but the habits which are specified in the culture as being best. . . . Thus an essential set of conditions for social learning is the behavior of the socializing agents. . . .

Before the analysis of teaching techniques is undertaken, several terms which are to be used should be defined. The terms "teacher" and "pupil" will be employed in a special sense, the former to mean anyone who attempts to change the habit structure of another

person, the latter, any person whose habit structure is being so changed. Although Kwoma parents most frequently play the role of teacher, with their children as pupils, the teacher-pupil relation is not by any means restricted to them. Co-mothers, siblings, paternal uncles, and aunts, and other relatives frequently play the role of teacher as well. . . .

Unless the essentials for learning are already supplied by the interaction of the environment and the pupil, they must be supplied by the teacher. In other words, when such conditions are not already present, the teacher, in order to change the habit structure of the pupil in the desired manner, must provide motivation, guidance, and reward. Each of the various teaching techniques employed at Kwoma may be classed under one or another of these three categories. The following table presents this classification:

1. Providing motivation
  - a. punishing
  - b. scolding
  - c. threatening
  - d. warning
  - e. inciting
2. Providing guidance
  - a. leading
  - b. instructing
  - c. demonstrating
3. Providing reward
  - a. giving
  - b. helping
  - c. praising

(J. Whiting 1941, pp. 177-178; 180)

An analysis of the method by which supernatural beliefs were transmitted in Kwoma society was also presented. This analysis was intended as an antidote both to some of the more exaggerated Freudian interpretations, which seemed to imply that the so-called projective systems of a culture were re-invented each generation from the neurotic fantasies of its members, and to the bizarre "racial unconscious" hypothesis, which held that religious beliefs were genetically transmitted.

Since learning theory was not especially useful as an interpretive device, the Kwoma example was not followed. However, as one of the bases for developing the so-called complex mechanisms of social learning, it was invaluable. Another and more profound influence of learning theory was methodological rather than substantive.

Learning and behavior theory was developed in the laboratory rather than on the "couch" or in the "field," and therefore the method used was experimental rather than descriptive and interpretive. The stating of hypotheses so that they can be tested or jeopardized is crucial to a laboratory science. Although the procedures of the controlled experiment are inappropriate for the study of socialization, correlational studies both within and across

cultures are quite feasible. The effect of work by the experimental-learning theorists was to introduce hypothesis testing, case counting, and the use of statistics to the study of socialization. John W. M. Whiting and Irvin Child expressed this development in their cross-cultural study of socialization:

Most previous work in culture and personality has been oriented primarily toward seeking concrete understanding of specific cases. Our work in contrast is oriented toward testing generalized hypotheses applicable to any case. The difference is not between interest and lack of interest in general hypotheses. The student who is primarily oriented toward full interpretation of the individual case inevitably makes use of general hypotheses as an interpretive device. But he is inclined to take their validity for granted and use them simply as tools which contribute to the understanding of the concrete case. We are not willing to take the validity of any hypothesis for granted until we see adequate evidence to support it, and we are willing to leave to the future the task of applying validated hypotheses to the interpretation of specific cases. (1953, p. 5)

### The comparative study of socialization

**Socialization as cause and as effect.** The Whiting and Child study used data from 75 mostly preliterate societies for which sufficient descriptive data on the socialization process were available. The hypotheses tested were derived from Freudian theory but modified by learning theory and adapted to the categories of cultural anthropology in such a way that they were testable.

In this study Whiting and Child made a distinction between the maintenance systems and the projective systems of a culture. The former include "the economic, political, and social organization of a society—the basic customs surrounding nourishment, sheltering, and the protection of its members" (Whiting & Child 1953, p. 310); the projection systems (Kardiner 1945) include magic, art, and religion. In any culture, socialization was assumed to be an *effect* of the maintenance systems and a *cause* of the projective systems. Thus, this model assumes that insofar as socialization affects the habit structure or personality of the members of a society, it becomes one of the mechanisms by which culture is integrated.

Following this study by Whiting and Child, a fairly large number of cross-cultural studies were undertaken to test hypotheses concerning either the effect of the maintenance systems upon socialization or the effect of socialization upon magical beliefs and rituals (these are reviewed in J. Whiting 1961).

Findings relating socialization to the projective systems include the following: the treatment of infants in a society is predictive of beliefs about the nature of the gods (Spiro & D'Andrade 1958; Lambert et al. 1959; J. Whiting 1959a); the severity of socialization leads to complexity in decorative art (Barry 1957); achievement imagery in folk tales is predictable from the age and severity of independence training (McClelland & Friedman 1952; however, in a replication of this study by Child et al. 1958, this relationship was not supported by the data); last, that an exclusive relationship between mother and son during infancy is associated with male initiation rites at puberty (J. Whiting et al. 1958; Burton & Whiting 1961).

Studies purporting to show that socialization is an effect of maintenance-system variables have found the following associations: the amount of indulgence during infancy is predictable from the number of adult females in the household—large extended family households being the most indulgent and households consisting of a mother and child alone being the least indulgent (J. Whiting 1961); extended family households are also the most severe in controlling the aggressions of their children (J. Whiting 1959b); the type of subsistence economy is predictive of the strength of socialization pressure to train the child toward being compliant rather than assertive, the strongest pressure being found among pastoral societies and the weakest among the hunters and gatherers (Barry et al. 1959).

**Comparative case studies.** Paralleling the type of cross-cultural studies reported above was a series of comparative case studies using the so-called method of controlled comparison. Margaret Mead's investigation of three societies in New Guinea—the Arapesh, the Mundugumor, and the Tchambuli—was the first of these (1935). In this study she concluded that the personalities of the two sexes are socially produced and may vary to the extent that the biological stereotype may actually be reversed.

A few years later the first large interdisciplinary project was undertaken. This was the Indian Education Research Project jointly undertaken by the Committee on Human Development of the University of Chicago and the United States Bureau of Indian Affairs. A long list of notables from the fields of anthropology, psychology, and education constituted the advisory committee. This ambitious project undertook the study of socialization and its effects upon personality in each of five societies: the Hopi, Navajo, Papago, Sioux, and Zuni. Standard tests such as the Rorschach, the Thematic Apperception Test, Stewart's Emotional Response

Test, Goodenough's Draw-a-Man Test, the Arthur Point Scale of Performance, and Bavelas' Moral Ideology Test were given to children, and the societies were compared on the basis of the test results. The major results of the project, however, were a series of descriptive monographs (Leighton & Kluckhohn 1947; Thompson & Joseph 1944; Macgregor 1946; Joseph et al. 1949). Although each of these was written by a different person, they provided far more comparable data than those which are usually available for the large sample cross-cultural studies.

In the above studies the society is the basic unit of comparison. Although in the Indian Education Project tests were given to individual children, the only intra-cultural comparison made was between subgroups judged to be more or less traditional.

Another project in which several societies were simultaneously studied—the Coordinated Investigation of Micronesian Anthropology—was undertaken shortly after the end of World War II. Although this project was not specifically addressed to studies of child rearing or personality development, several excellent studies on these topics resulted, notably one on Ifaluk (Burrows & Spiro 1953) and one on Truk (Gladwin & Sarason 1953).

The advantage of these projects, as compared with the cross-cultural studies based on large samples, was that they provided case studies in greater depth and with greater comparability; however, they suffered from providing too few cases to enable a confident interpretation of observed differences.

**Replication studies.** The next step in research-design efficiency was taken by Prothro (1961), who went further than using standard instruments for comparative purposes. He set himself the task of replicating, in Lebanon, a study of child-rearing practices that had been carried out in a suburb of Boston by Sears, Maccoby, and Levin (1957). The same interview was used as a basic research instrument. Some of Prothro's findings confirmed the Boston study, and some did not:

If we compare the children who did have feeding difficulty with those who did not, we find that the first conclusion of the American study is confirmed by our data. Feeding problems for Arab and Armenian children were not linked to infant weaning problems or to age at weaning. The feeding problems of the five-year-old—New Englander or Middle Easterner—are not linked to problems of feeding and weaning in infancy.

The relationship of maternal warmth to feeding problems is, however, the opposite of that found in America. The warmer mothers were more likely to report feeding problems. Of those mothers whose children had feeding problems, 47 per cent were high in warmth and 37 per cent were low in warmth. Of mothers not

reporting any feeding problems, 35 per cent were high in warmth and 45 per cent were low in warmth. This distribution . . . could not have occurred only by chance. Maternal warmth was associated with more feeding problems. . . .

It is not difficult to adduce post hoc explanations for the difference between our findings and those in America. American mothers generally try to see that their children eat enough, and eat a "proper" diet. Warm and cold mothers alike would concern themselves with what the child ate, and the warmth or coldness would express itself in the way in which they tried to achieve this goal. In Lebanon, however, there is less attention given to the diet of the toddler, so that greater warmth might express itself in greater concern for diet, more efforts to insure the eating of "healthful" foods, and more awareness of any balky or "finicky" habits that did exist. Thus greater warmth might produce pressures comparable to those found in America. Whether this explanation is correct or not, we can be certain of one fact—the [negative] correlation found in the United States between maternal warmth and feeding problems does not obtain in Lebanon. Warmer mothers reported more such problems. (1961, pp. 83–84)

As can be seen from the above quotation, the replication strategy is powerful when the results of various studies confirm one another, but when they do not, further replications are required. Large-scale comparative studies with carefully controlled methods of data collection and replication and a large enough sample of societies to adequately jeopardize a hypothesis have yet to be undertaken.

**Subsystem replication.** An alternative strategy that Roberts and Sutton-Smith have called subsystem replication has much merit. This design requires that any hypothesis to be tested be put in double jeopardy, that is, tested on the basis of cultural differences among an adequate sample of societies and also on either subgroup or individual differences within one or more of these societies. Studies involving socialization variables and using this strategy have been done by John W. M. Whiting (1954; Whiting et al. 1966a) and Roberts and Sutton-Smith (1962).

The most elaborate attempt so far to use the subsystem-replication strategy was the so-called Six Culture Project, which was directed by Irvin Child, William Lambert, and John W. M. Whiting. For this study teams of investigators underwent training in standard methods of interviewing and observing children for a year before going into the field. At the end of this training period the senior investigators and the field teams prepared a document, *Field Guide for the Study of Socialization* (Whiting et al. 1966b), for the purpose of maximizing the uniformity of their data collection. In

addition, Beatrice Whiting acted as a clearinghouse during the period of field work and attempted to solve unanticipated field-work problems in a way that would maximize uniformity.

The design of this study called for collection of cultural data on each of the six societies, using standard ethnographic techniques for comparison at the societal level. For subsystem replication, a sample of 24 children from the ages of three to ten, balanced by sex and age, was chosen at random from the census of all children in the community selected for study. These children together with their parents were chosen for intensive study. (See B. Whiting 1963 for a description of the cultures and the child-rearing practices and Minturn & Lambert 1964 for a factor analysis of standard interviews with each of the sample mothers.)

Although the effort to insure comparability of data collection represented by this study is a step forward in the comparative study of socialization, there is still a long way to go before satisfactory standards are achieved. Perhaps the next step will be the collection of a limited amount of data relevant to the testing of a specific hypothesis, carried out by a single person or team, on an appropriate sample of societies.

Anthropologists, stimulated by the work of Freud, have in increasing numbers turned their attention to the problem of cultural transmission. Ethnographies detailing this process, almost wholly absent in 1920, are now a commonplace. This has added what might be termed a "third dimension" to the description of a culture. More importantly, it has introduced an appreciation that the "natural man" assumption is inadequate for a complete understanding of cultural integration. The evidence from comparative studies of socialization indicates that man as a bearer of culture is not just a primate who thinks logically or prelogically and whose feelings are based upon primary needs such as hunger, thirst, sex, fear, and the like; in addition, as a consequence of the child-rearing methods of his society, man has blind spots and distortions in his cognitive processes and specific anxieties which may form the emotional underpinning and *raison d'être* for elaborate rituals and magico-religious beliefs.

### III

#### POLITICAL SOCIALIZATION

Narrowly conceived, political socialization is the deliberate inculcation of political information, values, and practices by instructional agents who have been formally charged with this responsibility. A broader conception would encompass all political learning, formal and informal, deliberate and unplanned, at every stage of the life cycle, including not only explicitly political learning but also nominally nonpolitical learning that affects political behavior, such as the learning of politically relevant social attitudes and the acquisition of politically relevant personality characteristics. For the present purposes we shall think of political socialization in the second, more comprehensive, sense.

#### The importance of political socialization

Political actions are determined both by the "objective" situations in which political actors find themselves (for example, the constraints and re-

wards imposed by the environment, including the structure of political institutions) and by the predispositions that citizens and their leaders have acquired through prior experience—*inter alia*, their political goals, expectations about the rules of the game of politics, conceptions of the legitimacy of men and institutions, group loyalties, assumptions about "human nature," and orientations toward authority. The nature of these predispositions and the processes through which they are acquired are matters of crucial political importance. For example, the political socialization process of a society may contribute to stability or instability, to continuity or change, to high or low levels of public political participation.

Socialization is an economical tool of government. To the degree that government relies upon the habituated responses of citizens, the necessity of environmental constraints is lessened. Authority is more stable when obeyed automatically than when sanctions must be threatened or employed. Yet it is not necessarily the stable, secure government that attends consciously and explicitly to political socialization. Rather, civic training becomes a deliberate policy when elements of potential instability are perceived in a political system—for instance, when an attempt is being made to weld together diverse and antagonistic populations into a single nation. Extensive formal political education also occurs where, as is the case under totalitarianism, the state carries on many of the functions ordinarily performed by other institutions, such as the family.

In the United States considerable explicit discussion of the importance of civic training can be found in the educational literature of the turn of the century, at which time sizable immigrant populations were being assimilated. Civic education is still considered a key function of the schools. Although detailed research has not been carried out, it seems likely that preoccupation with formal civic education and the inculcation of patriotism in the United States is greater than in Britain, but less than in an unstable democracy such as France, and certainly far less than in the Soviet Union, where "character training" and child-raising practices, as well as specifically political education, are officially discussed in terms of the requirements of the state (Bronfenbrenner 1962).

#### The study of political socialization

Scholarly interest in political socialization is coeval with the beginnings of political theory. It is difficult to think of a political theorist who exceeds Plato in his concern with the training of citizens.

[illegible]

These strategies of internationalisation starting after the war (1945) in the five states and their allies have been described traditionally as regional policy, not as global strategy. The formal documents of the planning were presented by a number of studies conducted by the American Historical Association (e.g. Nathan 1954, Flors 1961) and the meaning of 'regional' was the subject of a series edited by Philip H. Barbour (1962) in 1962. In 1962, the United States is said to pursue 'regional' development, 'consisting of efforts to promote self-sufficient and economic development. An important aspect consists of making significant advances in performance within each economic area, and to ensure that development efforts (Gardner & Lerner 1965: 101) [are] directed either towards either from the starting of their creation by the development of primary sources, especially studies of the political development of strategy and adjustment. During the period of the late post-war economic boom in the world in that region (Gardner 1966).

1. The present study was conducted in the following manner:

Although there is no primary interest in itself in the fairly important surrounding world, there is rather an inwardly self-regarding attitude, which is expressed in the following passage of *Lebensweisheit* (Knowledge of the Great Masters of Occultism), vol. III: "I regard what is mine more as mine than almost anything in which others are interested. I am selfish, I am egoistic, I am egomaniacal, and I am egomaniacal with a vengeance." (The translation will be somewhat more exact than the original, but the sense will be the same.)

For the purpose of this study, the following definitions were used. The term "social capital" was defined as the "resources of trust, reciprocity, and cooperation among individuals and organizations that facilitate collective action" (Putnam, 1993, p. 167). The term "social capital" was also defined as "the ability of a community to act together to solve problems" (Coleman, 1988, p. 30). The term "social capital" was also defined as "the ability of a community to act together to solve problems" (Coleman, 1988, p. 30).

1. The first step is to identify the problem or question that needs to be answered. This involves understanding the context and the specific requirements of the task.

upper social strata are more politically active than members of the lower strata. Research on children's political awareness, showing that these differences have already begun to be revealed by the age of age, indicates that there are no limits to social variation. Sex differences in political activity, too, seem to be encouraged by the entire psychological sex typing. Beginning with play activity, male children learn to be more sensitive to aspects of the environment beyond their personal needs and to be more active in their response to the environment. The political activity of young children, thus, reflects a socialization process from the young and male sex towards a greater awareness of the social and political environment. It is not clear, however, whether this socialization process is a function of the social and political environment or whether it is a function of the child's sex.

The volume is printed using University of Toronto's new "green" paper that is made from recycled material. The authors also express their appreciation for the support of the University of Toronto's Faculty of Education and the Ontario Ministry of Education. The authors also thank the many people who helped them with the book, including the many people who helped them with the book, including the many people who helped them with the book.

1973

agency for advancement of viewpoints related to party politics, but the schools are exposed to the general societal process of political and politically relevant communication and persuasion. Interest groups—industries, professions, liberal and conservative associations, patriotic societies, ethnic groups, agencies of government—vie for a hearing in the classroom. Groups provide teachers with instructional materials, send speakers to schools, and take an interest in the content of textbooks. (These groups also, of course, have direct programs designed to convey their views to children and adults.) From the earliest grades, schools purvey the symbols of nationalism through observance of holidays, teaching about national heroes, and patriotic ceremonies.

If the schools transmit communications from the entire range of societal institutions, so also do the mass media. The latter are extraordinarily important agents of political socialization. In the early 1960s the average American grade school child spent approximately twenty hours weekly viewing television and additional hours being exposed to other media (Witty et al. 1963). Many of the communications thus received are without specific political content, but some contact with political information is unavoidable. And children deliberately seek information about certain dramatic political events. The long-run effect of media attention is probably to build up, gradually and inadvertently, an awareness of basic elements in the political system.

There is much research suggesting that face-to-face communication in a primary group setting (family, peer group, neighborhood) is more persuasive than communication through the mass media. The study of political socialization supports this view strongly. In particular, the family is a vital source of socialization, especially in the acquisition of beliefs and loyalties. We have seen the apparent significance for French politics of the failure of families to serve as agencies of political communication. In the United States there is a high correlation between the political beliefs, especially the party preferences, of parents and those of their children: children acquire either partisan loyalties or the tendency not to have partisan loyalties from their parents (Hyman 1959; Greenstein 1965, chapter 4). Parents also have a powerful effect upon their children's motivation to participate in politics.

**Circumstances of political socialization.** All of the principles governing the effectiveness of educational practices and, more generally, of communication and persuasion, apply to assessing the effects of the various circumstances under which

political socialization takes place. A circumstance of political socialization alluded to above is the age at which learning takes place, including the sequence of learning.

That early learning is of decisive importance is suggested by many contemporary psychological theories and by traditional folklore. But the effects of the early formation of politically relevant personality structures may be attenuated or obliterated by later experience. Almond and Verba (1963) find a stronger correlation between disposition to participate in politics and feelings that one is free to participate at his work place than with feelings that earlier in life one was free to participate in the classroom or the home.

In the case of specifically political learning (in contrast to politically relevant personality development), there is evidence for the considerable importance of early experience. Political orientations learned during the initial school years or the late preschool years often have a greater impact on the individual's adult political behavior than do orientations that are learned later in life. For example, party identification is formed early in life; ideological orientations come much later. In the United States at least, the voter's party preference has a stronger effect on his electoral decision making than do his views about political issues. Children learn earlier about political executives than about legislative bodies. Among adult citizens there is more awareness of the former than of the latter and probably a tendency to attribute greater importance to executives such as the president, governor and mayor than to their legislative counterparts.

One aspect of this is the learning sequence. The concepts, information, and feelings that are first acquired serve as "filters" through which later perceptions must pass. Thus the child who "knows" that he is a Democrat, without attributing any substantive meaning to his party preference, will learn to orient himself toward the utterances of Democratic politicians and to acquire issue commitments consistent with his initial loyalty. The child who first becomes aware of a political executive and later learns of the existence of a coordinate legislative body may tacitly assume that the legislature is in some way ancillary or subordinate to the executive. Apart from its sequential effects, early learning may be important in and of itself because it takes place at a plastic, formative stage of development when critical capacities are limited. Adult orientations that have their roots in early learning and that have therefore been adopted without conscious consideration of alternatives, are likely to have an unquestioned character that

makes them both influential for behavior and resistant to change.

The effects of political socialization. Political learning has effects on the later political behavior of the individual exposed to socializing influences and, by extension, upon the political system. Most commonly, socialization seems to have conservative consequences for existing political arrangements. We have seen, for example, that class and sex differences in political participation tend to be transmitted from generation to generation. The conservative effects of socialization are not necessarily in the direction of encouraging political stability; political socialization in both stable and unstable societies is likely to maintain existing patterns.

Nevertheless, socialization is a potential source of change. It is always possible that the link will be broken in the attempt to transmit one generation's predispositions to the next. And since the training of the young is in part future-oriented, one generation may deliberately inculcate the next with values that differ from its own (Inkeles 1955). More generally, wherever different generations are exposed to different experiences, the seeds of change are present.

#### IV

#### ADULT SOCIALIZATION

Every society is faced with the task of socializing its children into the basic culture and, to varying degrees, of providing further socialization of these persons as they move into different statuses at different stages in the life cycle. In the simplest terms, one can say that through socialization the individual acquires the culture of his group or groups. This includes two main divisions of culture: the traditional positions, or statuses, in the society and the role behaviors associated with them.

The socialization that an individual receives in childhood cannot be fully adequate preparation for the tasks demanded of him in later years. As an individual matures, he moves through a sequence of statuses corresponding to different stages in the life cycle. In addition, his interpersonal environment may change because of geographic or social mobility with consequent demands for new kinds of behavior. Even though some of the expectations of society are relatively stable through the life cycle, many others change from one position to the next.

It would seem desirable from society's point of view to be able to socialize an individual in childhood so that he could successfully handle all of the roles he would confront in the future. Perhaps this is possible in a relatively unchanging society with little mobility where one could have foresight about an individual's path through the whole life cycle. But this orderly state of affairs usually can-

not be achieved; it can only be approximated to varying degrees, from one society to the next. Society can do no more than lay the groundwork for the necessary learning in later life, when the child will be confronted with the as yet only dimly seen adult roles.

There are, to be sure, other reasons why childhood socialization may be ineffective in later years. One major cause is that the demands for behavior at different stages of the life cycle may conflict (Benedict 1938). There are many other causes. In any given case, the individual himself may be unable to learn the necessary skills. Again, there may be agents missing, as in the absence of a parent or key institutions or agencies. The process can also fail because subgroups with deviant values exist in every society, and they do not prepare the child for the performance of the roles expected of him by the larger society at a later date. Finally, the specific socializing agent, such as a parent, to whom socialization is entrusted by society, may be inadequate to carry out the task because he himself is not interested or because he is ignorant or emotionally disturbed.

**Adult socialization.** For analytic purposes, a typology of adult socialization can be constructed in such a way as to display the origins of the need for each type.

Consider first the individual who is confronted with a new role and knows virtually nothing about what he should do. In such a case society will require new socialization, two types of which can be distinguished. The first of these is socialization which is *legitimate*, in the sense that it is recognized as needed by society and the individual is not expected to have learned the role earlier. This is true of individuals moving through a sequence of student roles, and of job training of certain kinds. The second type can be referred to as *illegitimate*, in the sense that the individual should have learned the role earlier. Examples here come with greatest frequency from the marital and parental roles: deficiencies which may have been caused by inattention to the person's socialization for this role on the part of his parents, or by a variety of other influences on the individual's early development. Where the need for new socialization is recognized as legitimate, one usually finds formal institutional mechanisms in society to provide it. These include schools, vocational training programs, and similar devices. Where the need is not legitimate, retraining institutions do not usually exist, although the fact that they do exist in some areas, such as family counseling programs, reflects a growing recognition that the individual is not always to be blamed for ignorance of this kind of role.

The other major class of adult socialization is concerned with *resocialization*. Here the individual knows something about the role in question, but what he knows is wrong. For purposes of symmetry one can divide resocialization into two types along the dimension used above: the legitimacy or illegitimacy of the need for the resocialization. This time let us mention the illegitimate case first, since it is the more familiar one. Resocialization here includes rehabilitation of the criminal, handling the young delinquent through environmental manipulation, and therapeutic work with middle-class neurotics; in all three cases, resocialization is designed to make up for earlier socialization of an unsanctioned kind.

The legitimate type of resocialization—where the individual was socialized, but in the wrong way, so that the resocialization is viewed as legitimate and hence is sanctioned by society—is a less familiar instance. This is seen in the change from an ideal conception of a role to a more realistic conception, as illustrated in the relation of professional training to later professional practice (Becker et al. 1961) and, more generally, with respect to childhood myths about how adults behave, which clearly are functional in maintaining stability in the early years but need to be dispelled in later years, when the child actually takes on the role of adult.

### Studies of socialization

Most work in the study of personality development has told us little about how an individual develops his reciprocal, socially regulated interactions with other human beings or how he comes to understand role prescriptions and to distinguish between the important statuses in his society. There are historical reasons for this. Most work on socialization has come from the field of child development. But the emphasis from the beginning, in the child welfare stations established after 1920, has been more on maturation than socialization, more on development than learning; most of the output has consisted of studies of mental and physical development, and only to a much lesser extent of studies of the social and emotional aspects of development. The stimulus to much of the current work on socialization came from a different source: the work of Freud and related theories of personality. The effect of early life experiences on the development of personality traits that were believed to be fundamental and enduring characteristics of the individual was the initial focus of study. It was later, around 1930, that concepts emerging from cultural anthropology, especially cultural relativity and the plasticity of human nature, extended the

scope of studies of personality and led to a convergence of the interests mentioned above. The traditional work on child development, combined with concepts stemming from clinical theories of personality and enhanced by cross-cultural perspectives, resulted in some notable studies of socialization by Sears and his colleagues (1957), Whiting (1963), Levy (1943), and others. This work, for all of its contributions to our knowledge, still did not deal with role learning as the content of socialization. It is probably for this reason that it did not lead to a consideration of personality change in later life.

Analyses of the socialization of children in the family are numerous. Variations in child-care practices have been catalogued and analyzed by hundreds of investigators. Reviews in this area include those by Hoffman and Lippitt (1960), Clausen and Williams (1963), Bronfenbrenner (1958), Brim (1957), and several chapters in Hoffman and Hoffman (1964). The attempts to find important basic dimensions for the classification of such socialization practices have shown fairly consistently for more than a generation that practices can be efficiently described by two fundamental dimensions: positive affectivity as opposed to negative affectivity, and dominance as contrasted with permissiveness. One can note that analyses of socialization of children are less concerned now with actual training methods, such as education regarding cleanliness or home duties, than with the qualities of the interpersonal relationships. The supposition is that characteristics of relationships—for example, the two dimensions described above—are more important for socialization effectiveness than are the specific educational techniques.

Traditional work within school systems on the socialization process has involved studies of the teaching process. A recent comprehensive report is by Ryans (1960). The great number of such studies makes it impossible even to comment on them here. Over the past several years Lippitt and his colleagues (Lippitt & Van Egmond 1962) have reconceptualized the study of classroom socialization and have opened up new and promising areas of research that parallel areas of study in the family and other nonschool socialization settings.

Compared with the amount of information available about earlier age periods, we have little knowledge about the older age groups. There is a paucity of research on the techniques of socialization for the marital and parental roles. The few analyses of techniques used in occupations include the work of Howard S. Becker and his colleagues (Becker et al. 1961). The work on formal education of adults that has been most valuable has been in

family-life education. Most of the studies of family-life education are highly valuable analyses of how one deals with adult socialization, and the observations made in these studies regarding methods used and the causes of change in adult personality are applicable to other adult socialization processes. These studies show the need to use group interaction as the context for learning and group interchange as the most effective method. This follows from the facts that the adult is not a *tabula rasa* and that the educational problem is one of change, of erasing what exists and substituting something new. A detailed analysis of these adult education methods has been made specifically for parent education (Brim 1959).

One can say, in general, that the value of our knowledge of socialization techniques lies in what it shows to be undesirable—in the information it gives us about procedures that produce resistance, repression, resentment, escape, withdrawal, and habitual behavioral conformity. But we still are far from knowing which methods are more effective than others in achieving the goals of socialization. We may know more about techniques of instruction in the educational field than in other socialization contexts; but here, since the main requirement of the student is that he acquire information rather than that he learn attitudes and motives, the problem may be simpler. In regard to the family, we seem only now to be learning some of the ways in which socialization procedures bring about a greater internalization of parental values. At the adult level the number of good evaluation studies are few in number and come mostly from the field of family-life education and mental health counseling (see Brim 1959). Our understanding of the differential effectiveness of techniques is still cloudy; effectiveness seems to depend on the nature of the content being transmitted, the characteristics of the persons being socialized, the persons' relationship to the socializing agent, and similar factors.

Studies would make a valuable contribution if they related techniques and their consequences to more general theories of socialization and of personality, and thus led to a general understanding of socialization, rather than remaining just narrow studies of the "effectiveness" of educational techniques.

### Limits of later-life socialization

The limits of socialization in later life are set, on the one hand, by the biological capacities of an individual and, on the other hand, by the burden of earlier learning. The effectiveness of later-life socialization is a consequence of the interaction of

these two limits, with the added limit of the types of socialization methods available to society. These methods depend, in turn, primarily on the knowledge available about human behavior and, to a lesser extent, on technological developments.

**Biological limits.** By and large, a society's demands upon adults are tailored to the capacities of the average man; individuals who, for biological reasons, fall substantially below this average are usually debarred from natural progression through the life cycle and, hence, do not often become liable to later-life socialization. There are, however, two ways in which biological restrictions lead to disabilities and thus to limitations on later-life socialization. The first of these occurs primarily in an open-class society with a high level of achievement motivation. Upward mobility into ever more demanding roles may lead an individual to positions whose demands he is unable to meet because of limited intelligence or strength, or other biological attributes. The second occurs when war and other disasters destroy society's protection of the individual from the direct impact of nature, and the culture is no longer fitted to the average man. Thus individuals who are biologically adequate for the roles they will meet in the course of their normal life cycles may suddenly find themselves unable to live under the new and primitive conditions.

**Limits of earlier learning.** There are several reasons why the effects of early experience place important limits on later socialization. In the first place, attitudes learned in childhood are especially durable because they are continually being taught and just as continually reinforced (Brim 1960). Second, there is good reason to believe that during early socialization the bulk of the unconscious material of the personality is accumulated. The continuity of the individual personality (and probably its characteristic modes of defense as well) is therefore maintained by the inertia, so to speak, of unconscious forces relatively inaccessible to change by later socialization. Finally, it has been suggested (Caldwell 1962) that the human life cycle, like that of subhuman species, may contain critical periods at which human beings must learn certain things if they are to develop further. Failure to learn these things during the appropriate period may make it impossible for subsequent learning to take place.

Whatever the usefulness of these or other theories, both biological and learning limitations on later-life socialization certainly exist, although their exact nature is not yet understood. Nevertheless, the powerful arguments for the potent effects of early life experiences should not deter the study

of large and important changes that may take place in later life. The fact is that actual evidence on the effects of early life experience has, up to now, been mostly of a case history nature, coming from clinical practice. Too little attention has been given to the study of those important changes which may occur after childhood as a result of socialization experiences. A few important studies have begun to appear (Hathaway & Monachesi 1961; Kagan & Moss 1962; Reichard et al. 1962; Neugarten et al. 1964); it is to be hoped that many more will follow.

**Relationship to the socializing agent.** The fact that childhood socialization is usually so much more effective than adult socialization can be explained partly in terms of the different types of relationships that typically obtain between the individual and the socializing agent or agency at different stages in the life cycle. The relationship between child and parent is a highly affective one; by contrast, the adult socialization context is likely to be far less charged with emotion—in Parsons' phrase (1951, pp. 59–61), it is characterized by "affective neutrality." Moreover, the parent socializing the child is likely to make a far more open and continual use of power, so that the child can hardly avoid realizing that it is the weaker party in the situation. Agents of adult socialization, on the other hand, typically appeal more to the reason and self-interest of the person being socialized, and use power only as a last resort.

There is at least one major consequence of this difference for the results of socialization: adult socialization limits itself, on the whole, to a concern with behavior rather than with motivation and values. In fact, it is less able to teach basic values and probably requires a relationship paralleling that of childhood to bring about equivalent basic value changes. This may indeed occur—an example is adult religious conversion, in which the submissive relationship and high affective interchange with the religious figure underlie the radical shift in the adult's value system (Frank 1961). Another example is the extreme one of prisoner-of-war camps. Work on "brainwashing" and the breaking down of resistance to enemy values shows the context to be one in which the captors use their extreme power in a deliberate manipulation of the whole range of affect—from rejection and hate, on the one hand, to support and positive sympathy on the other—thus bringing the prisoner into a position similar to that of a child with his parent. [See BRAINWASHING; INTERNMENT AND CUSTODY.]

It follows that if society is to undertake basic re-socialization of adults in respect to motives and

values, it has to institutionalize in some form the high power and affectivity relationship characteristic of childhood learning.

### Changes in socialization content

The substantive content of socialization differs, of course, in important ways at different stages of the life cycle and in different major social institutions. Since both the needs for and the limits to socialization vary by life-cycle stages, it is probable that the types of content vary accordingly. I propose that we distinguish five major types of change in socialization content, as follows.

Perhaps the most important change is the shift in content from a concern with values and motives to a concern with overt behavior. Society assumes that the adult knows the values to be pursued in different roles, that he wants to pursue them with the socially appropriate means, and that all that might remain to be done is to teach him what to do. Thus society is willing to spend much less time in retraining adult motivation and values than in training children; it is understood that teaching basic values and motivations is a necessary task of the institutions serving children, especially the family, and they are organized to carry out this task.

Why should this difference exist? Probably it stems directly from the limitations on later-life learning that make it impractical to attempt a thorough resocialization. It may be that the costs are too high and that it simply is not efficient, from society's point of view, to spend too much time on teaching an old dog new tricks. Perhaps only in the case where the need for a certain kind of manpower is very great and the question of efficiency becomes secondary to the need for personnel can an intensive and costly resocialization effort be made for adults.

Society has at least two major solutions to this problem of resocialization. One is anticipatory, with attention being given to the selection of candidates for an adult organization. In order to screen out those who do not have appropriate motives and values for the anticipated roles. This helps to assure that those who enter the organization will not present difficult problems to the socialization program. In this way adults probably do get sorted out, more or less, and placed in social situations where they fit best in terms of the values and motives learned in their early life socialization. Hobbs 1963. A second solution is that society may accept conforming behavior alone as evidence of satisfactory socialization and may forgo any concern with value systems. This entails risk, for if the social

system undergoes stress, then the conformity, since it is superficial anyway, may break down rapidly.

The second of the changes in socialization content might be described as a change from the acquisition of new material to a synthesis of old material. As a person moves through the life cycle, he accumulates an extensive repertoire of responses, both affective and behavioral. These are organized in terms of roles and, at a more specific level, in terms of episodes within a role. These responses can be detached from the contexts in which they have been learned and used, and joined with others in new combinations suitable as social behavior responsive to the new demands of adulthood. One can say, therefore, that the content acquired in adult socialization is not so much new material as it is the aggregation and synthesis of elements from a storehouse of already learned responses, with perhaps the addition of several fragments that are newly learned when they are necessary to complete the complex social act demanded in a given situation. Socialization in the later-life stages seems to emphasize the practice of new combinations of skills already acquired, rather than teaching wholly new complexes of responses.

The third change in the content of socialization is the transformation of idealism into realism. As the individual matures, the society demands that he become more realistic and lay aside his childish idealism. The change in the content of expectations involves distinctions between statuses. Early learning encompasses the formal status structure; later learning takes into account the actual status structure, which may often be informal and unavowed. One designates as cynical a person who doubts that the actual and the formal are divergent; on the other hand, we think of a person as naive if he does not make this distinction. In socialization the young child is not taught much about the informal system, thus, in early years he may believe that the actual and the formal are nearly identical. This serves to maintain and legitimize the formal status differentiations and to protect them from change. However, as the child matures, the realistic aspects of status differentiation also must be taught if the system is to work effectively.

Closely related is learning to distinguish between ideal role prescriptions and that which is actually expected of one in a role. Here, as in the case of status differentiations, the inculcation of ideal role prescriptions results in a desirable idealism that strengthens and perpetuates the ideals of the society. As the child matures, he learns to take his part in society in terms of the realistic expecta-

tions of others rather than in terms of conformity to ideal norms.

The fourth type of change in socialization content is to a greater concern with teaching the individual to mediate conflicting demands. As one moves through the life cycle, he is forced to develop methods of choosing between conflicting role prescriptions. The possible conflicts between the expectations of reference set members can be classified into two main types. First, there is *intrarole* conflict, in which the expectations for performance of two or more individuals, or of one individual with respect to different aspects of the role, are in conflict. In the first instance, a man's wife and his employer may differ in their expectations of his performance on the job; in the second, the wife may expect her husband to be both companion and taskmaster to his son. Second, there is *interrole* conflict, which can also be classified into two subtypes: where the conflict is between two or more individuals with respect to two separate roles, as when the employer's demands for job performance conflict with the wife's demands for familial performance; and where the conflict is between the expectations of one individual for performance in two different roles, as when the wife has conflicting expectations for her husband's behavior at home and on the job.

The need to learn how to handle such conflicts occurs to a greater extent in later life for at least two reasons. First, if the cultural norm is that children should be protected from seeing life's conflicts, then it follows that nothing will be taught about ways of mediating them. Second, in later life there are more roles, as well as more complexity within roles, so that there is a much greater possibility of role conflict.

Thus, as one ages, he learns the ways of conflict resolution, which Ralph Linton (1945) once described so well: avoiding the situation, withdrawing acceptably from conflict, and scheduling conflicting demands in temporal sequence, so that the conflict disappears. In addition, one learns another very important method of conflict resolution, which I think has been overlooked. The fact is that in every society there are recognized prescriptions for solving certain kinds of conflicts that arise from the competing demands of reference set members. These prescriptions, which have been called "metaprescriptions" (Brim & Wheeler 1966), govern the resolution of conflict between demands on one's time and loyalties, and they usually, although not always, pertain to interrole rather than intrarole conflict. Examples of metaprescriptions are "Do what your employer asks of you, even if it means

that you have little time for your children," or "Side with your wife when she disciplines the children, even if you think she is wrong." It seems to me that a noticeable change in the content of socialization in later-life periods is the attention given to ways of resolving conflict through such metaprescriptions.

The fifth characteristic of change in socialization content is in the dimension of generality-specificity. In the context of the current discussion, this means that what is taught in socialization may apply either to many social situations or to just a few. The dimension of generality versus specificity can be applied to both components of role prescriptions, that is, to both values and means.

As a child, the individual is trained, both deliberately and unwittingly, by socializing agents in the goals and behavior appropriate for his sex. There are male and female styles of doing many different things, and these are learned early. Society tries to motivate the child to perform the behavior and to pursue the values expected of him, and it trains him in the necessary skills. These characteristics are general, in the sense that they are required in a variety of situations he will confront in society, either as major components or as necessary coloring of other aspects of his behavior.

The case is similar for cultural differences in basic values, such as those related to achievement, to other persons, to nature and the family, and indeed to all of those general value orientations, to use Florence Kluckhohn's phrase (1948), that help to distinguish between major cultural groups. They are acquired early (and, in contrast with sex roles, with perhaps less deliberate instruction), and they give shape and tone to the performance of many roles in society.

The individual is socialized for his socioeconomic position, or the style of life of a certain status level. In other words, he acquires general skills and values, appropriate to carrying out in a certain manner a number of specific role demands for behavior. The values and behavior characteristic of a subcultural group are usually acquired in childhood (C. Kluckhohn & Murray 1948; Miller & Swanson 1960; F. Kluckhohn & Strodtbeck 1961), and, as with sex roles and basic cultural values, some part of what is learned is gained outside of any deliberate formal training program. Socialization into a new social level or style of life occurs in later life also; for example, one function of certain college organizations, such as fraternities, is to carry on this kind of socialization into a social class level higher than that of the individual's family or origin. The existence of socializing agencies with

this function can be seen as a response to the legitimate need for resocialization that results from the upward social mobility in American life. [See REFERENCE GROUPS.]

### Deviance and social control

Deviance can be defined as failure to conform to the expectations of other persons. Since there are always groups with different viewpoints in society, what is regarded as deviant from one person's frame of reference might be considered conformity by another. Thus, whether an individual's behavior or values are deviant always must be determined by reference to the viewpoint of some particular person or group.

Deviance has its cause in an individual's ignorance, or his lack of ability, or his lack of motivation; and it may occur in behavior, or values, or both. We can recognize two major underlying causes of ignorance, inability, and lack of motivation (excluding biological limitations to effective socialization, such as low intelligence). One major cause is ineffective socialization of the individual for the performance of the roles expected of him, even though the social systems in which he lives have been relatively unchanging. The second major cause is a shift in what is expected of an individual resulting from social change and leaving the individual in a situation where his prior socialization, although quite adequate for performance with reference to the old role prescriptions, no longer serves him well.

The modes of attempted control over deviance reflect a society's predominant theories and assumptions about the causes of deviance and are rooted in basic ideas about human nature: for example, whether man is inherently a stupid animal, whether he is possessed by demons or controlled by other supernatural forces, whether he is innately depraved and burdened with original sin, and so on.

In our own society it is deviance in motivation and values that is viewed as most serious. The concept of motivation plays an important role in our theories of why human beings act as they do, and deviance in motivation is viewed as a serious threat to the social order. Thus there is a tendency to examine instances of deviance for possible motivational components in order to appraise how serious the deviance is. In return, the deviant person, challenged as he is to account for his behavior and faced with punishments for motivational deviance, which are customarily greater than for deviance of other types, will plead ignorance or lack of ability as cause of his actions. The result is that considerable time is spent, in both the courts of

law and the systems of informal social control, searching for possible motivational deviance behind the façade of ignorance or lack of ability. As an answer to the difficult problem of identifying the motivational component in deviance, we often seem to begin with the assumption that the cause is in fact motivational. Perhaps another reason for this a priori assumption is that it places the "blame" on the individual for his behavior, rather than upon society.

The burden of proof thus is placed upon the actor to show that his motives are pure. The demand that he do so is legitimate from society's viewpoint, since it is difficult to distinguish the actual existence of ignorance or lack of ability from hypocritical claims that one did not know what the rules were or that he was unable to live up to them. However, there is a price for using this approach to the resocialization of deviant persons. The treatment of deviance would be more effective if it made use of techniques that accord with the causes of the behavior: education, where ignorance is the cause; improved training, where lack of ability is the reason; and, where motivation is the problem, a planned and deliberately executed program of manipulation of rewards and punishments that would reorient the individual to the appropriate goals and behavior. If deviance comes from ignorance or lack of ability, and yet punishment is given in the mistaken idea that motivation is the cause, then a frequent result is the individual's rejection of the values of society that he formerly accepted.

The concern with motivation and the burden of proof for motivational purity is less in the early stages of the life span. Once again, this is true both of the informal family systems and, at least in American society, of the courts of law. Probably the reason is that time remains to train the child, and the socializing agencies remain in firm control of adequate rewards and punishments to influence the course of a child's interests. With each advancing year, however, instances of deviant motivation are viewed with more seriousness, and the child's responsibility for motivational conformity increases in accord with the age-graded developmental schemes that are accepted in his culture, until the full-scale responsibility of adulthood is demanded of him.

## SOCIETAL ANALYSIS

The social sciences consist of methods, concepts, theories, and findings whose ultimate point of reference is human society in general. While most of their ideas and data have thus far been produced by students of Western societies, social scientists aspire to use these ideas and data as means of analyzing or illustrating more general phenomena. Since aspiration often outruns achievement, especially in man's attempts to understand himself, unwarranted generalization from Western experience is still common; but it is now generally recognized in principle—and both the increasing numbers of non-Western social scientists and the increasing concern with data drawn from non-Western socie-

ties illustrate this—that the enterprise is a common, panhuman one.

The inclusion in this encyclopedia of a series of articles on the societies of many (but not all) regions of the modern world represents a recognition of both the universality to which the social sciences aspire and the difficulty they experience in achieving it. If universality were easily achieved, such separate treatment would be unnecessary. The article on area studies recounts the recent efforts by universities, governments, and foundations to achieve a less parochial perspective [see AREA STUDIES]. The present article explores the nature of the difficulty to which these efforts are directed and describes the continuing role of the analysis of particular societies in social scientific inquiry.

### Universality and relativity

The universalistic, generalizing element in the social sciences is the legacy of the Enlightenment view of mankind as essentially unitary, a view which, significantly enough, had as one of its products an encyclopedia. From this perspective, what is characteristically human is what all men have in common: their capacity to shape their own futures through action guided by self-conscious thought, or, in the Enlightenment idiom, "reason." The social sciences themselves become the scientific disciplining of this self-direction in the pursuit of a converging future for all men. However, running alongside this universalistic, rationalistic view in postmedieval social thought, and often intertwined with it, is another vigorous and venerable standpoint which locates the distinctively human in the amazing variety of sociocultural worlds which human communities have created for themselves. If man is rational, he also lives within historically given sociocultural complexes which condition and direct his rationality. It thus becomes the task of social science to analyze the *diverse particular* societies and cultures within which human self-direction must operate.

These two views confronted each other most starkly in the great political debates which preceded and followed the French Revolution: for the Encyclopedists, particular societies and cultures were the creatures of oppressive governments and obscurantist churches which "natural" reason should seek to strip away in the interest of common "natural" rights; for Edmund Burke and other writers of the conservative reaction, rights and reason could find expression and meaning only within the "natural" framework of historically given religious and political institutions (Parkin 1956).

Political debates aside, the paradox is still with us in the form of the continuing tension in the social sciences between the notion of cultural relativity and that of the "psychic unity of mankind."

While the paradox has not been resolved—indeed, perhaps, cannot be resolved, since it is inherent in the subject matter of the social sciences—it is now somewhat better understood. Studies of man's biology have demonstrated a common human ancestry and a common capacity to create culture—or at any rate have found it impossible to demonstrate the reverse (Dobzhansky 1962; Washburn 1963). Studies of language have demonstrated the common capacity of all known linguistic systems to mediate culture and to intertranslate (Hymes 1961). At the same time, our contemporary understanding of man's emergence from his primate ancestry suggests that the very freedom, relatively speaking, from genetically encoded patterning of behavior which makes possible his self-conscious self-direction renders him particularly dependent for behavioral patterning upon systems of shared public symbols—"cultures"—which are highly variable and are characterized by complex internal organization (Geertz 1962; 1965). Furthermore, since the social sciences themselves are systems of shared public symbols produced by men in society, the social scientific enterprise cannot entirely escape the cultural-historical relativity which conditions human social life in general (Mannheim 1929-1931). Both human social life and our attempts to understand it are thus products of a continuous interaction between man's captivity within distinctive cultural worlds and his capacity to manipulate, and in part transcend, such worlds.

The aspiration and capacity to transcend, both in social life and in our analyses of it, are particularly prominent today. While the many distinctive cultural traditions were far from mutually isolated in the past (McNeill 1963), today, it is generally agreed, their interaction has reached a level unique in human history. The major "civilized" traditions, and even most of the nonliterate "tribal" ones, are now in intimate and continuous contact through movements of persons (including social scientists) and through new means of long-distance communication. First, in the context of Western imperial and quasi-imperial domination, and more recently in that of a world system of formally sovereign but mutually dependent nation-states, a potentially common pool of technology, ideas, and organizational forms has come into existence. Whatever dangers and opportunities this may present to mankind as a whole, it confronts social scientists with the paradox of relativity and

universality in new and more poignant forms: How can the social sciences, still deeply conditioned by a preoccupation with Western societies and their historical experience, understand both the continuing cultural diversity and the seemingly convergent processes of change exhibited by a world community of societies that are increasingly interconnected ecologically? In particular, how are we to view the contemporary development of those societies outside the north Atlantic homeland of the social sciences, whose behavior and fate at present so engage the attention of both social scientists and men of affairs? How far are concepts that have been lifted out of Western folk sociology and put into the technical vocabulary of the social sciences—concepts such as family, political party, feudalism, and law—adequate for a truly comparative social science? What is the most promising strategy for developing more adequate ones?

One example may serve to illustrate the difficulty. The studies of occupational prestige conducted by the National Opinion Research Center in the United States have been repeated in many other countries, both Western and non-Western, with results which appear to be strikingly similar in the sense that the same occupations appear to have very similar relative prestige in all industrial and industrializing societies (Inkeles & Rossi 1956). However, there is much debate concerning the meaning of these findings. Do they mean that there is a system of social stratification characteristic of all industrial societies and that this structure has an internal logic of its own which operates independently of particular cultural settings? Or does the selection of occupation as the focus of prestige build into these studies an essentially Western stratification configuration, thus masking the differences in meaning which different cultures may give to similar organizational forms (Lipset & Bendix 1959, chapter 10; Fallers 1964, pp. 117–121)? No doubt the answer lies somewhere in between, but this is hardly an adequate conclusion, for the territory "in between" is vast. As Western social scientific techniques and concepts are increasingly extended to other societies, such problems may be expected to proliferate.

#### Comparative macrosociological perspective

One strategy for meeting some of the difficulties just described is the comparative macrosociological one. This approach is "holistic" in the sense that it takes seriously the interrelatedness of elements within sociocultural wholes. It need not involve assuming the impossible task of dealing exhaustively with all aspects of a sociocultural whole, nor

need it imply the view that the human social world is divisible into functionally discrete, self-sufficient systems (see Levy 1952, chapter 3). It does, however, require an attention to the larger sociocultural context of the particular elements under study and an attempt to conceptualize such contexts. The logic of such an analysis is more clinical than generalizing; instead of using the data of diverse particular societies to test a broad generalization, it brings together diverse general ideas in the attempt to understand particular societies. In the context of the social sciences as a whole, of course, it contributes to generalization because the application of general ideas to particular societies is a means of testing their adequacy. Even though its central subject matter may be one society, an analysis in this genre is always either implicitly or explicitly comparative because the general ideas of which it makes use have their origins in earlier attempts to understand other societies, or even the same society at an earlier period.

On purely scientific grounds, such an approach is supported by our appreciation of the consequences for particular institutions and collectivities of involvement in larger-scale units (Steward 1950). Apart from this, however, the organization of the contemporary world into populist nation-states and clusters of states confronts men everywhere with the practical necessity to think analytically about such large-scale social units. Africans and Europeans, Russians and Americans are urged by their governments to support policies toward one another as units—policies informed by understandings which, however adequate or inadequate, are inevitably macrosociological.

Of course, different styles of comparative macrosociological analysis are possible. One—the bolder—is represented by the various recent attempts by social scientists to leap out of history and to construct, in a burst of creative imagination, a universally applicable conceptual scheme for the comparative analysis of all societies (Parsons 1951; Levy 1952) or particular aspects of all societies, such as the political (Easton 1953). Another, less ambitious, style involves the comparison of particular societies or aspects of societies, case by case, in the effort to test more limited propositions (e.g., Bendix 1956). [*These and other differences in comparative studies are discussed in ANTHROPOLOGY, article on THE COMPARATIVE METHOD in ANTHROPOLOGY; POLITICS, COMPARATIVE; SOCIAL INSTITUTIONS, article on COMPARATIVE STUDY.*]

Both of these styles have contributed substantially to the development of a more adequate comparative perspective for the social sciences; which

of them one pursues depends upon how seriously one takes the relativity side of our paradox—how impressed one is by the cultural-historical distinctness and “given-ness” of particular societies and, hence, by the difficulty of arriving at universal categories. The regional articles in this encyclopedia, by their very nature, contribute to the less ambitious style in comparative macrosociology. These articles differ rather widely in focus and in analytical explicitness; but they all represent attempts to deal in a social scientific way with large-scale units, and they all employ intersocietal comparisons in an effort to increase our understanding of the societies under study. Often, either implicitly or explicitly, they employ concepts taken from Western thought about Western societies, and they thus raise the question of the explanatory power of such concepts in different cultural-historical settings. It may be suggested that explicitness in these matters is a virtue and that a self-conscious reference to the Western roots of our ideas and methods can contribute to the success of the comparative enterprise. Before discussing some of the propositions which emerge from the regional articles, therefore, it is appropriate to recall the historical context in which the macrosociological perspective emerged in Western thought.

**The emergence of the perspective.** The preoccupation with sociocultural differences is as old as the social sciences themselves, as Aristotle's comparative studies of constitutions and Herodotus' accounts of the institutions of non-Greek peoples show. One can, however, trace the immediate intellectual ancestry of contemporary comparative macrosociological concerns to more recent origins in the reflections of Western intellectuals upon their own past as they entered the postmedieval world of accelerating social change. There are, to be sure, gems of Western-non-Western comparison to be found in the literature of the Renaissance and the Enlightenment, such as Machiavelli's perceptive analysis of the French and Ottoman politics ([1532] 1941, pp. 104-105). For the most part, however, early modern intellectuals' interests were so seized by the revolutionary transformations occurring in their own societies that they used the data of non-Western societies (especially the non-literate societies of which they were being made aware by the voyages of discovery) more for the purpose of allegorical speculation upon the roots of their own institutions than for serious comparative analysis. It was the increasing awareness of change within Western societies and the growing knowledge of their ancient and medieval pasts produced by new historical scholarship that proved

most fruitful for comparative macrosociology until almost the end of the nineteenth century. The comparative perspective which emerged was one concerned with developmental stages in time rather than with differences and similarities among contemporary societies. However, as the Western societies achieved world dominance, especially in the nineteenth century, and as Western intellectuals became more conscious of their societies' preeminence, the comparative mode of thought was extended to the non-Western world, which was often seen as representing stages through which the West had passed. The Western experience came to be viewed as the end of history—a paradigm for understanding the experience of non-Western societies.

The classics of early comparative macrosociological thought were centrally concerned with characterizing and analyzing the new institutional complexes which set the societies of their day apart from those from which they had emerged. To mention only a few of the landmarks: Hobbes and Bodin sought to understand the nature of the new sovereign, secular state; Adam Smith analyzed the conditions for the politically autonomous market economy; Tocqueville considered the significance of increasing popular participation in politics; Marx traced the consequences of the separation of labor, under the system of industrial production, from the personalistic ties of kinship and feudal patronage; Weber considered the causes and consequences of the pervasive development of bureaucratic organization. From these studies emerged a set of conceptual models of the characteristic institutions of modern societies.

Other writers in this vein sought, through broad developmental typologies (“custom” and “reason,” “status” and “contract,” *Gemeinschaft* and *Gesellschaft*, “mechanical” and “organic”), to grasp intellectually the changing nature of whole societies. While there were occasional doubts among writers of this genre about the universal applicability of their developmental schemes—Marx, for example, considered the possibility of a distinctive “Asiatic mode of production” as an alternative to feudalism in precapitalist societies—on the whole, the question was either ignored or handled by assimilating non-Western forms as earlier stages. Nineteenth-century anthropology, while it contributed some classics of ethnographic description, was generally cast in a similar intellectual mold.

For some other Western intellectuals, the experience of radical social transformation stimulated thoughts of quite a different kind, both in relation to their own societies and, later, in relation to the

prominent role in both political and economic life. The author of the article on Japanese society concludes, *contra* Veblen (who in this instance represents the earlier view that the modernization of the West is paradigmatic), that this combination may be a relatively stable one and that it may be necessary to recognize a distinctively Japanese "modernism."

China is less fully modern in the economic sense, but the recent revolutionary transformation of Chinese society under an ideology drawn from one stream of Western experience poses an equal challenge to comparative understanding. As the article on Chinese society shows, a persistent problem for students of the Chinese revolution has been the question of whether the revolution is "essentially Marxist" or "essentially Chinese," i.e., whether it represents a basic change in society and culture along Marxist lines or a nationalist reassertion of traditional Chinese identity [see CHINESE SOCIETY]. The author acknowledges important elements of continuity but argues, in Weberian terms, that the emergence of a new dominant culture-bearing collectivity (the party) suggests a fundamental transformation. Incidentally, his discussion of the older dominant group, the "gentry," raises the question of the adequacy of this term, taken from English history, for understanding the premodern Chinese situation. The article on southeast Asia raises similar questions concerning the appropriate models for conceptualizing the structure of premodern societies in that area [see ASIAN SOCIETY, *article on SOUTHEAST ASIA*].

Several of the regional articles raise the question of the nature of the state in areas in which state and nation are in radical discontinuity. The model of the state assumed by the modern Western institutional paradigm is one in which a culturally and linguistically united people—a nation—is governed by a political institution possessing a monopoly of ultimate power within its boundaries and autonomy vis-à-vis other states (Kohn 1944; Jouvanel 1955). Although modern Western experience contains numerous exceptions to this model (Belgium and Switzerland have contrived to maintain states comprising culturally diverse groups, while as imperial powers several European states have exercised varying degrees of sovereignty over dependent polities, both within and without Europe), still the model has been felt to be paradigmatic in the sense that there is a strain toward sovereignty (decolonization) and, especially as populist politics develop, toward a coincidence between political and cultural boundaries (nationalism).

Today this conception is being tested in the ex-

perience of the new states and in social scientists' analyses of this experience. On the one hand, as the article on sub-Saharan Africa shows, the new states of that region—the new "global societies"—typically contain many formerly autonomous societies whose present political and cultural unity is mostly the result of European colonial rule [see AFRICAN SOCIETY, *article on SUB-SAHARAN AFRICA*]. On the other hand, the Arabs, whose present-day societies are analyzed in the article on north Africa and in one on the Near East, find their sense of linguistic, cultural, and religious unity violated by political fragmentation [see AFRICAN SOCIETY, *article on NORTH AFRICA*; NEAR EASTERN SOCIETY, *article on THE ISLAMIC COUNTRIES*]. Once united with non-Arab coreligionists within the mosaic empire of the Ottomans, they have achieved political independence but not political community. However "artificial" and "unstable" they may be, modern state boundaries in Africa and the Near East have proved highly resistant to change in response to ideological stirrings, suggesting that organizational forms may take on a life of their own that is independent, to some degree, of cultural forces.

Yet another pattern of state formation is illustrated (perhaps "constituted" would be the better term, in view of the uniqueness of the case) by Israel, a society formed through the recolonization of their homeland by a religious community dispersed for two thousand years throughout Europe and the Islamic world. Culturally and linguistically differentiated by the Diaspora, the Jews nevertheless retained sufficient sense of community, first to form a cohesive organizational structure across existing political boundaries and then, around this structure, to establish and defend a territorial base. [See NEAR EASTERN SOCIETY, *article on ISRAEL*.]

While the regional articles are far from supporting the notion that the present-day development of the non-Western world may be understood as simply a process of "Westernization," Western imperial influence has nevertheless been an important factor in the history of most societies outside Europe, and these articles therefore provide much material for the comparative study of imperialism. For the Old World non-European societies, imperialism represents an interlude—often far-reaching in its consequences but an interlude nevertheless—in histories in which the elements of continuity are indigenous. For the societies of the New World, however, the imperial imprint has been much more decisive. Even in Middle America and South America, where there were some large-scale indigenous societies with highly complex cultures, European

immigration was so massive and its cultural impact so profound that the resulting contemporary societies are more accurately viewed as American variants of Iberian society than as modernized or Westernized native American ones [see MIDDLE AMERICAN SOCIETY; SOUTH AMERICAN SOCIETY]. In the societies of the Caribbean, continuity from the indigenous past is still more tenuous. Populated largely by persons of African slave descent, these societies remain variously Spanish, English, and French in dominant language and culture and "colonial" in socioeconomic structure [see CARIBBEAN SOCIETY].

In the article on Anglo-American society we have a thoroughgoing comparative analysis of a European imperial society and its daughter societies overseas. Utilizing Parsons' scheme of pattern variables, the author analyzes the variations upon common sociocultural themes which arose in Great Britain, Canada, Australia, and the United States and concludes that today these differences are declining in response to common developmental trends. [See ANGLO-AMERICAN SOCIETY.]

Continental Europe, whose intellectuals have played such a central role in the development of the social sciences and whose societies have provided so much of their data, occupies a special place in comparative macrosociological studies. From one perspective—the one stressed here—its common sociocultural features have provided a paradigm for the comparative study of other societies. But while these common features are real enough, so that one might speak of the region as a "culture area" in the anthropological sense, it is (like other regions) internally differentiated in ways that invite comparative study on a more detailed level. This perspective is represented in this encyclopedia by the articles on various sociocultural complexes that are historically characteristic of Europe, such as democracy, socialism, communism, capitalism, Christianity, bureaucracy, political parties, and labor unions, all of which are analyzed comparatively. Indeed, much of the content of this encyclopedia, both substantive and conceptual-theoretical, is at least implicitly concerned with intra-Western comparative analysis. [See BUREAUCRACY; CAPITALISM; CHRISTIANITY; COMMUNISM; DEMOCRACY; LABOR UNIONS; PARTIES, POLITICAL; SOCIALISM.]

Of all the regional articles, the one on south Asian society gives least attention to the problem of cultural continuity and discontinuity [see ASIAN SOCIETY, *article on SOUTH ASIA*]. Acknowledging that Indic and Islamic cultures continue to inform the societies of the area, the author argues pro-

vocatively for an austere social structural analysis in terms of levels of complexity. This analysis of south Asian society also reminds us that models for comparative investigation are today drawn from diverse areas. While the author implicitly draws upon Western models for the analysis of the more complex levels of south Asian society, his frame of reference for analyzing village and tribal communities, he says, is derived from social anthropological studies of Africa. The study of south Asian society, in turn, has provided at least one model whose applicability to other societies social scientists have found it enlightening to explore. The article on the concept of caste, the area's most distinctive sociocultural complex, examines the south Asian phenomenon, compares it with others and, in a manner which well exemplifies the logic of comparative macrosociological analysis, reformulates it so as to elucidate intersocietal similarities and differences [see CASTE, *article on THE CONCEPT OF CASTE*].

The native societies of North America [see INDIANS, NORTH AMERICAN] and of Australia [see OCEANIAN SOCIETY] have been so displaced by European immigration that the article on Anglo-American society, which gives an account of the modern societies of these areas, can completely ignore them. The island societies, still under colonial rule, are perhaps destined for some sort of independence, a situation which, if it develops, will test some of the hypotheses suggested in the article on "small societies" [see SOCIETIES, SMALL]. While of little immediate relevance to the comparative study of contemporary national societies, research on these societies has been extremely productive of ideas which have influenced comparative macrosociological thought, for it was in relation to them that Malinowski, Boas, and Radcliffe-Brown developed the new anthropology, which emphasized holism. As the articles mentioned above show, continued anthropological research on these societies has produced a rich literature of comparative analysis, both synchronic and diachronic.

### The future

The scholarship which underlies the regional articles is the fruit of the great post-World War II expansion of the social sciences' concern with the non-Western, or "developing," world. Much of this activity has been carried out in the context of "area studies" programs, interdisciplinary programs of research and training organized around regions of the world characterized by common cultural traditions. In terms of the dialectical pattern of development in comparative macrosociological studies outlined above, the emphasis during this period has

been on the relativizing side: in an effort to make their social scientific concepts and theories more relevant to the task of understanding non-Western societies, many social scientists have become Indologists, Africanists, or China specialists as well as, or even in some cases instead of, social scientists. Recent developments suggest that today at least a partial reversal in emphasis may be in progress. As the results of specialized regional studies become more readily available to the social scientific community at large through secondary works of synthesis, somewhat more ambitious styles of comparative analysis again become profitable.

In the vanguard of this movement have been the students of economic development—the economists and economic historians, who have all along reached for generalization more persistently than other social scientists have. Few economists have become "area specialists." The reason for this is, of course, quite simple. From the time of Adam Smith to the present, the criterion of economic growth in monetary terms has provided economists with a relatively unambiguous standard about which to organize data for intersocietal comparison. Thus, while some, like Gerschenkron (1962), Hirschman (1963), and Rosovsky (1961), have become deeply engaged with the data of particular societies, their work has articulated directly with that of such generalizers as Bauer and Yamey (1957), Lewis (1955), and Schultz (1964).

For other social scientists, at any rate insofar as they have not been centrally concerned with the sociocultural prerequisites or concomitants of economic growth, there exists no such universal standard. Although a number of writers have attempted to conceptualize a "modernity" toward which all contemporary societies aspire or are tending (Shils 1959-1960; Kerr 1960). It is widely recognized that tradition remains a crucial element in all societies and that consequently there are likely to be many paths toward the future. Thus, for example, the analytic scheme proposed by Levy (1966), perhaps the most elaborate and rigorous in the recent literature of comparative macrosociology, is much more differentiated and open-ended than those of most nineteenth-century writers. The Western paradigm has been thoroughly relativized.

Levy's work is directed toward the comparative analysis of whole societies; much more common are comparative studies of particular aspects or institutions such as Janowitz's study of the military (1964), Apter's volume on politics (1965), and Lenski's work on social stratification (1966). Given the rising standards of regional scholarship, much

comparative work is, of necessity, collaborative. The volumes produced by the Committee on Comparative Politics of the Social Science Research Council (Almond & Coleman 1960; Conference on Communication . . . 1963; LaPalombara 1963; Conference on Political Modernization . . . 1964), the Committee for the Comparative Study of New Nations of the University of Chicago (Chicago . . . 1963; Johnson 1967), and the Congress for Cultural Freedom (*Democracy* . . . 1959; Bellah 1965) exemplify recent efforts to achieve comparative perspective through seminars and workshops of regional specialists.

Finally, as non-Western studies have matured, there has developed a discernible tendency toward completing the circle of comparative analysis by bringing their results to bear upon the history of the West. Lipset (1963) has re-examined the United States as "the first new nation," Moore (1966) has compared the historical role of agrarian organization in Europe and Asia, and Palmer (1959-1964), in his monumental study of the Western revolutions of the late eighteenth century, has felt it appropriate to comment upon the relationship between the events with which he is concerned and those of the twentieth century in the non-Western world. Bendix (1964) has compared the development of authority and citizenship in western Europe, Russia, India, and Japan, Eisenstadt (1966) has analyzed comparatively movements of protest and processes of change in the West and in the "third world." This article may therefore end with the observation with which it began: the road toward a more universal perspective for the social sciences leads through the study of diverse particular societies, considered comparatively.

## SOCIETIES, SMALL

"Small" is obviously a relative term. When applied to societies it usually refers to area, population, or both; for purposes of sociological analysis a distinction must be drawn between a small-scale society and a small territory. It is possible to have a small-scale society in a very large territory (e.g., the Eskimo or the Bedouin). It is also possible to have part of a large-scale society in a very small territory (e.g., Luxembourg or Monaco). The criteria of size for territories are area and population; the criteria of scale for a society are the number and quality of role relationships. In a small-scale society the individual interacts over and over with the same individuals in virtually all social situations. In a large-scale society the individual has many impersonal or part-relationships. As Mair puts it, "Every member of the large-scale society is party to a great number of relationships, some ephemeral, some lasting, which do not overlap" (1963, p. 13).

Sociologists and social anthropologists have treated "smallness" in terms of the small groups found within a society. Usually this has been termed the "primary group" or the "face-to-face" group. Sometimes the general characteristics of such groups have been the focus of interest (e.g., Homans 1950); sometimes it has been the study of particular types of groups, such as the family (e.g., Bell & Vogel 1960), the gang (e.g., Whyte 1943), or some other form of association. Such face-to-face groups exist in all societies and are not a particular characteristic of small territories.

The study of "small-scale" societies has been the particular concern of social anthropologists. Indeed, smallness in scale has been cited as a distinguishing feature of the subject matter of social anthropology (Firth 1951, p. 17) and as a defining characteristic of "primitive" (Evans-Pritchard 1951a, p. 8). One should distinguish between two major types of small-scale societies. Both are composed chiefly of primary groups, but in one the total social field is small and in the other it is composed of a series of interlocking similar small groups which

extend through a considerable population. Island societies such as those on Tikopia (Firth 1936) or Dobu (Fortune 1932) are examples of the former type. The latter is exemplified by the segmentary societies such as the Nuer (Evans-Pritchard 1940; 1956), the Tiv (Bohannon 1957), and the Tallensi (Fortes 1945; 1949). Nadel has constructed the model for this type of society:

Think, for example, of a tribe divided into a number of sub-tribes or extended families; these all duplicate each other, both in their structure and their modes of action; each is relatively self-contained, and such relations as obtain between them (intermarriage, economic cooperation, and so forth) do not follow from their constitution (their "statutes"), but are contingent upon circumstances and outside interests. Though such segments may in fact "combine" to form the society at large, they could exist without each other and in any number; one could add to or subtract from it without affecting the working either of each segment or of the embracing group. (1951, p. 178)

Societies of this type are characterized by what Durkheim (1893) called "mechanical solidarity." Thus it is that the Tiv of Nigeria, who number perhaps a million, can still be described as a small-scale society.

The question arises as to whether such peoples as the Tiv are a "society" at all. This depends on the criteria we use to define society. There are a large number of possible criteria, such as common language, descent, origin, religion, political allegiance, and so forth. Most anthropologists would accept the criterion of the widest effective political group, i.e., the group that could employ force against outsiders and that effectively prevents or limits the use of force within the group (see Nadel 1951, p. 183-188; Mair 1962, part 1; Schapera 1956, chapter 1).

One other type of small group frequently studied by anthropologists and sociologists is the village community. Redfield has stressed the following as characteristics of the small community: distinctiveness both from the observer's and the inhabitant's point of view, smallness, homogeneity, and "all providing self-sufficiency" (1955, p. 4). Yet it is obvious that a village community is only what Kroeber ([1923] 1948, p. 284) called a "part-society." It is less self-sufficient than either the island society or the segmentary society, although, of course, there are considerable variations in this respect. [See VILLAGE.]

Scale and roles. The number of roles to be played in any society is to some extent dependent on its size, but size alone in terms of population does not mean that there are large numbers of dif-

ferent roles to be played. This is demonstrated in the populous segmentary societies. There must also be what Durkheim termed a condensation of society, multiplying social relations among more individuals and leading to a greater division of labor (1893). While the division of labor need not take place in a large population with a simple economy (as in the segmentary societies), it is more difficult for it to occur in very small-scale societies. Such societies may have a considerable proliferation of roles in the politico-ritual sphere, but they have very little specialization of economic and technical roles. Thus it is not only in the numbers of roles but also in the kinds of roles that small-scale societies differ from those of larger scale.

In their discussion of scale, the Wilsons state: "A Bushman, we maintain, is as dependent on his fellows as an Englishman, but the Englishman depends upon many more people than does the Bushman" (1945, p. 25). Yet it is obvious that there is a difference in quality in the dependence of the Bushman and of the Englishman on his fellows. The Wilsons describe this as a difference of intensity of relations, the intensity of the Englishman's relations being "more spread out."

The word "intensity" is by no means clear. The Wilsons imply that there is some total store of intensity which is invariable for all societies, but that it has various distributions in different societies. As the range of interrelations increases, the intensity of relations with near neighbors, etc., decreases. This is very difficult to prove, because we are not sure how intensity is to be measured. One could argue that the intensity of relations between spouses in London was greater (Bott 1957) than in a society in which, as in that of the Bushmen, there was greater dependence on neighbors and kinsmen. We can carry the analysis further than this by looking more closely at the nature of the roles themselves. Not only are there fewer roles in a small-scale society but also, because of the smallness of the total social field, many roles are played by relatively few individuals. It is a commonplace in anthropological studies of small communities that economic, political, religious, and kinship systems are very often congruent or nearly so. The same individuals are brought into contact over and over again in various activities. "Different types of primary groups tend to coincide or overlap in large measure" (Firth 1951, p. 47). Relationships are what Gluckman calls "multiplex," in that "nearly every social relationship serves many interests" (1955, pp. 18-19). Parsons (1939; 1951) has characterized such role relationships, which he terms "particularistic," as being affec-

tively charged. There are strong positive or negative attitudes between individuals involved in them. They also extend over a considerable time span. Such roles are usually ascriptive. The standards of judgment in the role depend on who the individual is rather than what he does. They are characterized by personal relations.

Particularistic relationships can be contrasted with impersonal relations. Parsons calls these "universalistic" because they are based on more or less fixed standards and criteria. The incumbent of a universalistic role treats all others with whom he comes in contact in terms of universal categories. A shopkeeper should treat all his customers alike, and a doctor all his patients. The roles are functionally specific in definition. The relationship, at least ideally in terms of a model, is affectively neutral. It also has a very limited time span, even though it may be repeated at intervals. The standards of judgment are based on criteria of achievement—what an individual does rather than who he is. Performance and efficiency, not ascribed hereditary qualities, are relevant. These are polar models, and it is obvious that both sets of features are characteristic of most role relationships which could be placed along a continuum. Role relationships change over time. As the same individuals continue to interact in the same roles, the relationship moves from the impersonal toward the personal pole.

In a small-scale society where the total social field is small, relationships tend to be personal. Who a man is matters very much more than what he does. For example, in business, professions, and government, family connections and friendships determine positive or negative attitudes; these are not based on role performances as shop assistants, doctors, and clerks. Occupational roles become diffuse when they have to be looked at in terms of kinship connections and influence in other spheres of activity. [See *ROLE*.]

**Values and alternatives.** An actor playing a role based on impersonal criteria is using one set of values, e.g., whether a customer owes one money; whereas the same actor acting in a personal frame uses another set of values, e.g., whether one's kinsman needs the money one loaned him. In a small-scale society one's customer is likely to be one's kinsman.

There is another sense in which the general values of a society may be related to its scale. Where kinship, economic, political, religious, and other systems tend to be coincident or nearly so, there may be a greater consistency of values than in a large-scale society, where there may be differ-

ent values for individuals acting in different situations or even for whole sets of individuals engaged in very different sorts of life (Redfield 1941). In a small-scale society anonymity is impossible. In a large-scale society, particularly in an urban setting, it is possible by moving, by changing one's job, name, or style of life. As there are more kinds of jobs and ways of life in a large-scale society, so there are more alternatives for the individual. In a small-scale society choice is limited, alternatives are few, and the choice of an individual may have considerable effects throughout the social structure. Degrees of social cohesiveness will vary from society to society even when we are only dealing with small territories. A society like that of Mauritius (Benedict 1961), with its different ethnic elements, each having its own religion and style of life, is less cohesive than the kingdom of Tonga. Yet both societies are rapidly affected by any major decisions or changes. A strike at an industrial plant in the United States has little immediate effect on most Americans; a strike at a sugar mill in Mauritius has very serious effects throughout the island, not only economically but also politically. Nearly everyone would be affected. Decisions in the economic, political, and legal fields have a pervasiveness in small-scale societies which they lack in societies of larger scale. Again, this is because people are connected with each other in so many different ways in a small-scale society. Similarly, natural disasters are more devastating in small-scale societies because their effects are so pervasive, not just on the physical environment but throughout the social fabric as well (Spillius 1957).

**Magico-religious practices.** The worship of local saints, deities, or ancestors is a characteristic of many small-scale societies and has been shown by anthropologists to be intimately bound up with personal relations within the community. This form of worship carries personal role relationships to a supernatural plane. Ancestors are an extension in time of the kin group and are intimately concerned with its welfare. Neglect of ancestors can bring misfortune in a way analogous to neglect of living relatives.

Social anthropologists following Durkheim (1912) have shown how such beliefs reflect and symbolize the solidarity of local groups, kin groups, or the whole society itself. Yet such beliefs may only symbolize the cohesion of small groups within a society of any size.

Ancestor worship is found in China as well as in small-scale societies. The notion of a high god is found in both large-scale and small-scale societies. Magico-religious practices may be an index of

the homogeneity of a society but not necessarily of its scale. It may be that very small-scale simple societies are more likely to be characterized by a single set of religious beliefs, but many small-scale societies (e.g., Guyana, Fiji, Mauritius) are remarkable for the diversity of religious beliefs found within them.

It is often assumed that secularization accompanies the growth of impersonal relationships (e.g., Redfield 1941; Wilson & Wilson 1945), but it is by no means clear how beliefs in witchcraft, sorcery, ancestors, or local deities are related to the scale of a society or whether and in what manner they inhibit the development of impersonal role relationships. The expectations that such beliefs would rapidly disappear with the spread of education and scientific knowledge have been frequently disappointed. [See MAGIC; RELIGION.]

**Jural relations.** Maine's distinction between status and contract and his famous dictum that societies have progressively moved from the former to the latter have relevance in any discussion of the sociological aspects of smallness (1861). Status in Maine's sense refers to personal role relationships. These depend chiefly on birth and who a man is. A number of anthropologists have pointed out (e.g., Bohannan 1957) that procedure in native courts is often devoted to finding out who the litigants are in terms of descent and affiliation rather than in finding out what occurred, for it is believed that an individual's behavior cannot be judged apart from who he is. The important thing is to restore good social relationships among all parties concerned (including the judges), not to conform to an impersonal law. Because of the multiple connections between litigants, lawyers, and judges in small-scale societies, there are often difficulties in applying impersonal law.

Contractual relations pose similar problems. In a contractual relation involving the payment of money, the only relevant question is whether or not the money is owed. It does not matter whether the creditor needs the money or whether the debtor can afford to pay. Where one is doing business with one's relatives, friends, and neighbors, it is difficult to apply impersonal standards. Questions of need and ability to pay may take precedence over the strict terms of the contract (see Parsons 1939). A shopkeeper having close personal ties with his clientele will find it very difficult to be an impersonal creditor, and this may well lead him into bankruptcy. It is common in many small communities for the shopkeeper, who is the principal manipulator of creditor-debtor relationships, to be an outsider, of a different ethnic or religious origin

from his clients. Thus he is not so closely connected to them by kinship and friendship ties, which enables him to be a more impersonal creditor and hence a more successful businessman (Benedict 1964, p. 344).

**Political structure.** Apart from external political factors, there are sociological factors affecting the political structure of small-scale societies. Foremost is the ubiquitousness of government. In a small-scale society one cannot progress very far up any occupational or prestige ladder without running into government. Government is an active party to nearly every sizable enterprise, not only officially but also because of the multistranded personal networks connecting the members of a small society to each other. In many technologically underdeveloped societies there are small elites marked off from the rest of the population by either ethnic criteria or class barriers. They often have control of the wealth and technical skill (including education) of the society. They usually have a large number of dependents or clients attached to them and are very often able to control the internal political machinery of the society. In small-scale societies the elite must necessarily be small. Opportunities for upward mobility are limited and more easily controlled by those in power—again because the social field is smaller. Obviously the homogeneity or heterogeneity of a society is important in this respect. Where factions form they are not apt to be simply on the basis of political issues, but extend to numerous social relationships. Where there are ethnic, religious, or linguistic differences, social cleavages may become even wider and more irreconcilable (e.g., Mayer 1963, chapter 12). Whereas in a large-scale society political relationships are only partial relationships, in a small-scale society they are much more inclusive. Closely knit family organization, personal ties within the community, traditional bonds of clientage or servitude, color bars, and so forth all militate against social mobility, whether in the political or the economic sphere.

The form of government as related to scale also deserves attention. A small governing elite is, after all, not a peculiarity of small countries. Literal democracy in the sense that everyone has a direct say in government can exist only in very small communities where everyone can meet and discuss a problem until agreement is reached (Mair 1961, p. 2). But even in small territories, with the exception of some of the very smallest islands, this is impossible. Representative government takes the place of democracy in its pure form. Theoretically, a small society with an informed electorate should

operate a representative democracy very well; but the multiplex ties connecting leaders to their followers mean that cliques or factions form which are based not on issues of policy but on ties of kinship and patronage. It is at least questionable whether very small-scale societies can successfully operate a party system. The small elites with multiplex relationships among their members may make it difficult for an opposition to develop. In a large-scale society politicians out of power can take leading roles in industry, local government, or the professions, but in small-scale societies there are relatively few such roles, and those that exist tend to be integrated with the governing elite.

For similar reasons small-scale societies often experience difficulties in developing an impersonal civil service. Civil servants form part of the governing elite. Their actions are apt to be seen as either supporting or opposing certain politicians. The network of multiplex personal relations makes it exceedingly difficult for an individual to play the role of a neutral civil servant. He is apt to be forced into partisanship (see Singham's article in Benedict 1967).

**Economic organization.** Large-scale or even medium-scale economic operations require functionally specific roles. If such enterprises are to be efficient and competitive they must be based on impersonal criteria of performance and achievement and not on an individual's personal ties with other individuals in the enterprise (United Nations 1955, p. 20). The affective component must be as neutral as possible or rational choices in terms of the efficiency of the enterprise become very difficult. Nevertheless, studies in industrial sociology have shown that where attempts are made to treat individuals as instruments rather than as individuals loss of efficiency often occurs and personal elements may have to be reintroduced (e.g., Roethlisberger & Dickson 1939). In large-scale societies there are always possibilities of bringing in outsiders. The social field is large enough to permit this. In small-scale societies outsiders must be imported from another society. Are there societies which are too small for impersonal criteria to prevail, and just how small is too small? Unfortunately, there do not seem to be any very clear-cut answers to these questions, although research could be designed which would give a more precise definition of the problem than we have now. For instance, a valuable question might be: What is the effect of the scale of a society on the specialization of roles within it?

Firth has mentioned (1951, p. 47) that there is less room for specialization of roles in a small-

scale society. This is particularly noticeable in occupational roles. Even should specialist techniques be acquired, there is simply not enough work for an individual to earn his living by his specialization alone. This situation has serious implications for economic development, for it means that a specialist must be trained and paid for performing only a very few services each year, or the society must import him at considerable expense and loss of time and at competitive prices when he is needed. Alternatively, the specialist must be a jack of all trades with the possibility that he may be master of none.

There remain questions about the type of economic enterprise and its relation to personal-impersonal pattern variables. The economies of small territories present few alternatives. They are almost invariably limited to producing a very few commodities which are exported to a limited number of markets. The domestic market is small, and local enterprise can rarely compete with cheap imports from mass producers elsewhere. Isolation from markets often aggravates the inefficiencies of personal role relationships. As the Wilsons have pointed out (1945, p. 25), there is a sense in which the scale of a society increases the more it is in contact with other societies. We need only compare Luxembourg with Mauritius, which is more than twice as populous, to see the cogency of this point. Unquestionably, the factor of development is significant. The underdeveloped countries, even the large ones, are socially characterized by personal role relationships. Their small elites reach into all facets of social existence. It can only be predicted that they have a larger potential social field for developing impersonal role relationships than the small isolated territories.

Industrialization appears to be most dependent on impersonal role relationships, while cottage industries, agriculture, and commerce seem to be less so. But some types of enterprise may thrive on a personal basis. Family businesses may succeed in risky enterprises simply because family members are not tied to the enterprise merely on the basis of a wage that they draw, but also by multiplex personal obligations, which may tide them over a period of economic difficulties. Whether a whole territory, even a small one, can succeed on such a basis is doubtful. A strong network of personal relationships or great social cohesion does not mean social harmony or common goals. The affectivity of such roles can be negative as well as positive. The intense factionalism of small communities has been observed repeatedly (Firth et al. 1957). Such

communities are no more cohesive and harmonious than groups found in large-scale societies.

What relation exists between small-scale societies defined in term of role relationships and small territories defined in terms of area and population? It is clear that small territories tend to be characterized by small-scale societies simply because of their relatively small populations. It is also clear that there are other factors involved, such as geographical isolation and economic and technological development. Luxembourg is a small territory, yet economically it exhibits large-scale characteristics as a result of its integration with its neighbors in the Common Market. Politically, however, it retains many characteristics of a small-scale society. Where there is greater physical isolation, as in the island societies of the Caribbean, the Pacific, or the Indian Ocean, the features of the small-scale society are even more marked. This is surely one of the sociological reasons attending the difficulties of federation in such areas as Indonesia, Malaysia, and the West Indies.

## SOCIETY

The concept of society has been formulated in various ways in sociological thought. At a general level there is some agreement as to the referent of the concept, but to abstract this common meaning from the welter of different and competing meanings of the term, we must first eliminate from consideration those usages which merely adopt the term as a shorthand label for the fabric of social phenomena in general. As the historical section of this article will show, the word is often used in this all-embracing sense. Indeed, "society" is frequently used merely to refer to an encompassing network of social relationships that enclose some more specific phenomenon which is the primary object of analysis. Thus, a student of race relations may insist that interracial behavior can be understood only as a part of the organization of the larger society in which it occurs and yet may fail to provide any analytical conception of the nature of this larger whole. It is only when analysts begin to isolate the attributes of the larger whole which we term "a society" that analytical treatments of the concept begin to emerge.

**Definitions of society.** Analytical definitions usually treat a society as a relatively independent or self-sufficient population characterized by internal organization, territoriality, cultural distinctiveness, and sexual recruitment. Specific definitions vary considerably in regard to which of these elements is emphasized. For example, some stress

internal organization so strongly that they define the society as consisting in the organization and not in the population. Definitions also vary in the specific meaning given to such concepts as "self-sufficiency," "organization," and "culture." Careful formulations must develop precise apparatus for specifying the units and boundaries of societies, for describing the nature of the links between units, and for establishing the mechanisms by which these links influence social processes within society. Nevertheless, the basic concept of the inclusive, self-sufficient group remains a constant element in most concepts of society.

When the concept of society is formulated in definitive detail, it is capable of entering into sociological thought in significant ways. Various conceptions of society define the essential problems of sociological analysis and thus shape conceptions of the subject matter of sociology.

The well-known functional conception of society put forth by Aberle and his colleagues will serve to illustrate a detailed concept of society and the way it enters into a system of sociological thought. According to these analysts, "*A society is a group of human beings sharing a self-sufficient system of action which is capable of existing longer than the life-span of an individual, the group being recruited at least in part by the sexual reproduction of the members*" (Aberle et al. 1950, p. 101). The authors proceed to specify four conditions that would terminate the existence of a society: biological extinction or dispersion of the members, apathy of the members, the war of all against all, and the absorption of the society into another society. These conditions enable the authors to specify the functional requisites of a society by enumerating the mechanisms that permit a society to exist, thus specifying the meaning of the core concept of a "self-sufficient system of action." If the conditions terminating the existence of a society are to be avoided, mechanisms must develop to insure provision for sexual recruitment, provision for adequate relationship to the environment, role differentiation and the assignment of members to roles, communication, shared definitions of the world and of the goals of the society, normative regulation of means and of emotional expression, socialization, and the control of disruptive behavior. Thus, the authors have proceeded directly and logically from a definition of society to a conception of the essential concerns of societal analysis, even developing along the way some relatively specific hypotheses. For example, it is proposed that extremely rapid social change, such as revolution, tends to be accompanied by increases in the

conditions terminating the existence of a society—mortality, morbidity, apathy, force, and fraud.

It is not surprising that definitions of society are so closely articulated with conceptions of the nature and functions of sociological thought, for from the very beginning of the analytical development of the concept, social theorists have found in "society" a convenient foundation for relating their specific problems to a larger context. Thus the student interested in elucidating the nature of bureaucracy may insist that it is embedded in a larger network of organization which determines, or at least influences, the emergence of bureaucracy and the forms which it assumes and which constrains purposive attempts to shape bureaucratic development.

If society is conceived as a set of external and constraining social forces, it is natural that the concept should be put to ideological use. He who would assert that some social institution ought to change or ought to be protected from change may point to the external and constraining forces of the larger society that encompass the institution, finding in those forces both an evaluative standard and an empirical justification for that standard. The emergence of analytical concepts of society has been inextricably bound up with the development of political ideology of this type.

### History of the concept

In the Western world the concept of society as an entity distinct from the state emerged rather late. The age of reason, when philosophers began to search for secular foundations for critical analysis of existing political institutions, was one of the earliest periods when Western thinkers came to view society as something clearly prior to and outside of the state. The vehicle used to establish this differentiation was the social contract doctrine.

**The utilitarian conception of society.** In some of its forms the contract concept failed to distinguish between state and society. Thus Hobbes, wishing to insist that there is no middle ground between an organized state and the war of all against all, treated the social contract, the law of nature, and civil society as virtually identical. But the liberal thinkers of the Enlightenment wished to justify secular rational criticism of the state. In developing a critical doctrine, such thinkers as Locke began to distinguish the law of nature from the social contract that had formed the state. For Locke there is a layer of natural order guaranteed by man's interdependence and his sense of the natural rights of all. It exists prior to and outside of positive political institutions; the state is a utili-

tarian device for insuring a more efficient, less cumbersome social order by developing specialized machinery for enforcing natural law. Such a theory squarely establishes the state as a dependent sector of a larger social order.

By a similar logic the critical philosophers sought to establish analytical distinctions between society and church and to separate church and state. The church was defined by reference to its utilitarian functions for the larger society, and these functions were distinguished from the functions of the state. Thus, through the use of the concepts "civil society" and "religious society," church and state were defined as analytical functional aspects of a larger society.

Despite the incipient emergence of the conception of society as a set of interdependent organized functions, the idea of society developed during the Enlightenment was not entirely satisfactory, for the ultimate premises of argument continued to be the same premises from which Hobbes had derived the war of all against all. Enlightenment thought was founded on the concept of reason. The method of reason is analytical reduction; complex wholes must be reduced to their fundamental particles and the whole reassembled by a process of deduction from the laws governing particles. For society, the particle is the individual, and the law governing particles derives from the most essential quality of individuals, their natural reason. Each man uses his reason to rationally pursue his chosen ends. Parsons (1937) has termed this conception of society "utilitarian" and has shown that the attempt to derive social coherence and order from the faculty of reason in the individual was unsuccessful. The utilitarians could protect their Achilles heel, that is, the problem of conflicting ends, only by arbitrarily postulating such metaphysical concepts as the "natural identity of interests," "natural rights," and "the spirit of sociability." [See UTILITARIANISM, *article on SOCIOLOGICAL THOUGHT.*]

The more perceptive figures of the Enlightenment—Hume, for example—recognized the inner weakness of the utilitarian conception. However, only a sweeping new movement of thought placed the concept of society on a less atomistic foundation.

**Romanticism and organismic conceptions.** In the latter part of the eighteenth century, and especially in the period after the French Revolution, many social theorists became disillusioned with individual reason and the reductive methods of the analytical philosophers. As the philosophy of romanticism became more influential, a conservative theory of society developed which stressed the

unity of the integrated whole. Society came to be viewed as an organic growth, embodying the practical and profound wisdom of convention and tradition. Being a cumulative organic product, society has an organic unity. Abstract analytical segments cannot be separated from the whole and arbitrarily changed; to do so is to destroy the complex interdependence of the web of social life.

Again we have a concept of society as a larger whole, containing within it the standards by which particular phenomena are to be evaluated, but in this formulation the concept was put to conservative use. By assuming that the totality has an integrated character, one can effectively refute demands for arbitrary and rapid change in the parts.

The organismic conception sharpened the concept of society as a set of interdependent functions (which was already implicit in the philosophy of the Enlightenment) and drew attention to a new element, cultural tradition, as a functionally necessary part of a society. The idea of a cultural order as a constituent element of a society was developed further by August Comte in the early nineteenth century. Comte sought to synthesize Enlightened and Romantic modes of thought. Accordingly, he incorporated into his sociological system elements of classic liberal thought, such as the idea of a level of order arising from man's natural economic interdependence, and the concept of a larger society from which government derives its legitimacy. At the same time he refused to derive the larger society from individual reason and the concurrence of interests. Drawing on organismic conservatism, he found in cultural tradition the specifically collective factor in society. For Comte, the formation of any society presupposed a system of common opinions about nature and man. The Enlightenment philosophers, by destroying the normative order of the religiously based society, had loosed anarchy upon the world. Comte argued that the reformation of society required the creation of a new, scientifically based moral order. Again we see an example of the ideological use of the concept of society. Society remains a set of external and constraining forces by which we are to judge the acceptability of political ideology. The concept enters into sociological thought as a set of fundamental premises from which we are to derive the social constraints on political action.

Comte's plans for the reconstitution of society revolved about ideas for the reconstruction of religious, familial, educational, and political institutions. Embedded in his program is a contribution to the conceptual elaboration of the idea of society. Comte did not believe that a bare consensus is a

sufficient condition for organized collective life. The consensus must be organized in an institutional order that symbolizes, teaches, enforces, and implements moral ideas and rules.

The belief that society is an institutional order which embodies a fundamental set of cultural ideas was prominent in another branch of romantic thought which might be termed "idealism." Idealism, which was especially prominent in nineteenth-century German thought, stresses the cultural distinctiveness of each society. A society reflects a peculiar *Geist* or spirit that is embodied in its distinctive traditions and institutions. The spirit of a society progressively unfolds in history. Once again the ideological implications are clear: proposals for change are to be evaluated according to whether they are consonant with the cultural distinctiveness of the larger society. [See the *biographies of BOSANQUET and HEGEL*.]

**The economic conception of society.** Marx was an heir to the idealistic tradition, and the concept of society entered into his thought in a similar way. For Marx, as for the idealists, the elements of a society are closely intertwined into a complex and distinctive whole. For Marx, as for his idealistic predecessor Hegel, society is undergoing continuous transformation according to a logic of immanent development. The ideological implication is that social action is to be judged in relation to its correspondence to the immanent forces of change within society. At this point the similarity to idealism ceases, since for Marx the notion of a spirit or *Geist* is as metaphysical an explanation for the collective as the utilitarian postulate of natural order.

According to Marx, society exists in the concrete relations between social groups and not in the concepts used by philosophers to summarize these relations. The *Geist* is a mere analytical construct of the observer. The real foundations of society and the real springs of social development lie in the economic relations between men. The idea that the society outside of state and church is largely economic in character did not originate with Marx. The original utilitarian conception of society had stressed man's natural economic interdependence as the source of order which is logically prior to the state. However, Marx developed the idea of society as an economy in rich detail.

The economic conception of society starts with the assumption that man's most fundamental problem is to provide for his material needs. To do so, man must cooperate with other men by entering into relations of production. Stable relations of production constitute economic structures. Economic

structures are variable, but they generally involve two crucial phenomena: the division of men into classes and the exploitation of one class by another. Stratification and exploitation make the continuing stability of economic structures precarious, and for this reason whole complexes of compulsive apparatus develop to support the economic order. The state, law, religion, and ideology function to bring temporary stability into inherently unstable situations. Since economic structure is more basic, it can be termed the "substructure" of society; and the supporting institutions may be termed the "superstructure," since they are derivative in the sense that they are responses to the problems of economic relations. In the theory of substructure and superstructure, we see one of the first and most comprehensive theories of society as an institutional order. [See *ECONOMY AND SOCIETY*.]

**Conflict theory.** The Marxian conception of society is one of a larger set of conceptions that can be combined under the heading of "conflict theory" (Martindale 1960). The premise of conflict theory is that men are organisms, and as such they must compete for access to the resources of life. The struggle for existence does not occur between isolated individuals but between groups. In various versions of conflict theory the competing units may be families, bands, classes, nations, or races, depending on the special interests of the analyst or the stage of social development under analysis. As the conflict between groups becomes stabilized or organized or regulated, we may speak of the emergence of a structured society. Society is viewed as an organizational device for relating populations of organisms to an environment, and in this sense conflict theory may be said to adopt an ecological perspective. In conflict theory the concept of society enters into sociological thought as a means of relating social life to natural forces. In this way social scientists were able to develop a less metaphysical, more naturalistic account of society than had been produced by either Enlightened or Romantic philosophers. [See *CONFLICT*.]

To see society as a device for regulating the struggle for existence and for relating man to his environment is not necessarily to renounce interest in cultural and normative phenomena. Sumner's classic account (1906) views society as a product of antagonistic cooperation between competing organisms and groups; but the phenomenon that emerges to stabilize, organize, and regulate cooperation is a complex of customs, mores, conventions, laws, and institutions. The theory remains naturalistic in insisting that normative complexes develop gradually and naturally as a response to environ-

mental problems. They do not emanate from cultural spirits, nor are they created *de novo* from a social contract.

Conflict theory is too general a rubric to imply any particular ideological purpose. It is apparent that some forms of conflict theory are susceptible to use in support of racial or nationalistic ideologies. It is less often remarked that conflict theory was often used in the development of liberal doctrines.

The perspective of conflict theory dominated sociological thought in the latter half of the nineteenth century. Its acceptance is closely associated with the impact of the Darwinian revolution in biology and the popularity of evolutionary modes of thought. It was in connection with the use of conflict theory as an evolutionary doctrine that sociological thinkers were able to place classic liberal ideas on a naturalistic foundation.

**Emergence of the "utilitarian society."** Nineteenth-century evolutionary theory was manifold, and its devotees worked out developmental sequences for every institutional sphere of society. Insofar as the evolutionary school had any common theory of the development of total societies, it was the idea of movement toward the development of larger and more inclusive wholes. By processes of consolidation, conquest, incorporation, and differentiation, societies come to increase in scale and complexity. As this occurs, unregulated conflict between small fractionated groups becomes less important, and the regulation of internal process becomes more important. Further, as the relations with the environment and other societies become more stabilized and the larger society becomes more consolidated, new forms of social organization become possible. Social organization can be built upon processes of free discussion, free exchange, and the pursuit of individual interests. The inflexibility of the "cake of custom" and rigid military organization becomes nonadaptive; only a looser framework of organization can improve the adaptation of society to the environment by unleashing the forces of creativity and innovation.

In this brand of evolutionary theory we see the re-emergence of the concept of the "utilitarian society." However, in nineteenth-century thought the concept was no longer used as an analytical definition of the nature of any society, but as an increasingly accurate description of a historically emergent form of society.

Not all of the social analysts writing at the end of the nineteenth century viewed the emergence of the utilitarian society with equanimity. According to some analysts, the breakdown of old forms of

organization meant the loss of what had once provided society with integration, coherence, and meaning. The utilitarian society, founded upon the industrial revolution, the capitalist system, and the market mentality, fails to provide for an ethical standard outside of the individual or a viable source of social cohesion.

In 1887 Tönnies incorporated this type of perspective into his famous dichotomy between *Gemeinschaft* and *Gesellschaft*. In the *Gemeinschaft* (usually translated as "community") men are held together by communal feeling and organic ties. In the *Gesellschaft* (usually translated as "society") organic ties are replaced by artificial ties of calculating self-interest. [See COMMUNITY-SOCIETY CONTINUA.]

Thus, from varied ethical perspectives and varied ultimate premises, social theorists came to conceptualize modern society as a mere collection of individuals united only through ties of self-interest. Spencer, working in the naturalistic tradition of conflict theory, and Tönnies, drawing on a more philosophical tradition, saw modern society as a collection of wills.

**The independent reality of society.** In 1893 Durkheim severely attacked both Spencer and Tönnies and reaffirmed the reality of society as an entity. Durkheim retained an evolutionary perspective; he accepted the notion of a developmental drift from a society based on very direct ties and commonalities to a society based upon more indirect interdependencies. However, he insisted that a modern society, founded on the extensive division of labor, cannot be conceptualized as a mere collection of the wills of isolated individuals. It is not a collection of contracts based upon self-interest; it is no less organic than earlier forms of society. It remains an entity *sui generis* (Durkheim 1893).

Durkheim wrote at a time when the young discipline of sociology was struggling for establishment in an academic setting. The problem for the sociologist was to establish the independence of his field from economics, political science, and psychology. Thus, it was essential to establish society as a set of external and constraining forces, more inclusive than the economic order, outside of the state, and independent of the sum of its individual members. Durkheim adopted the strategy of stressing the independent reality of such social facts as vital rates, currents of opinion, and established conventions. Social facts require explanation at their own level. It follows that society is an entity which cannot be reduced to a set of members or a set of economic contracts between members. It exists in the complex relations and interdependencies which

unite its members into an organic whole and which in turn are reflected in a collective consciousness and a collective moral order. Persons who are drawn together in a web of interdependency interact as moral beings and create a body of collective representations of reality and regulative rules. The resulting complex regulates the utilitarian economic order and the actions of persons and is external to them.

Other analysts of the era developed similar techniques for identifying the reality of the social. Simmel found a social level in the mutual influence that interacting persons have upon each other. Mutual influence comes to have coherent forms, and thus, as people interact, they create society ([1902-1917] 1950, part 1).

Weber, although he insisted on relatively nominalistic definitions of collective entities, developed a perspective of the social order that gave a somewhat independent reality to social processes. As persons orient themselves toward each other, social relationships form; complexes of social relationships constitute a social order. Drawing upon Tönnies, Weber suggested that when actors take a rational orientation to each other, they create a *Gesellschaft*, whereas when they adopt communal solidary attitudes, they form a *Gemeinschaft*. But in either case the resulting social order is not a mere collection of wills or economic interests, since it is given stability by administrative organization, shared orientations to systems of status, and shared beliefs in the legitimacy of the order (Weber [1922] 1957, part 1).

**The social-psychological approach.** In the United States a social-psychological school emerged which found in the concept of symbolic interaction the key to the integrated treatment of society and the social person. Cooley, Mead, and others explored the development of personality and society as they emerge through interaction. Their analysis permitted a novel conceptualization of human society as a symbolically regulated process. Mead, for example, traced the process of becoming a social person. The human being comes to acquire a social personality as he learns to communicate symbolically. As he learns to adopt the perspectives of others toward himself, he is also learning to regulate his own activity symbolically by defining his self and his acts in appropriate ways. It is through participation in that complex of differentiated and interrelated roles called "society" that we develop our distinctly human capacities and identities. It is through adopting, playing, and imaginatively construing social roles that we develop social personality. Thus, self and society are intimately con-

nected through the concept of *role*. Further, the analyst may make the transition in either direction; he may stress either socialization, that is, the process by which the individual organism is socially formed, or he may stress the process by which interacting persons create and transform society. The human capacity for symbolic control over action and sympathetic understanding of the action of others makes it possible for men to innovate, to appreciate innovation, and to incorporate innovations into complex networks of symbolically regulated activity (Mead 1934).

**Society as process.** The developments of the decades when sociology emerged as a discipline can be summarized by reaffirming that the most sophisticated analysts converged on the idea that society is ultimately an organized process. If society is more than the sum of its individual participants, its reality must lie in the organized relations that emerge as men interact. The units of these relations are not people but activities. Even Durkheim, with his insistence on the independent reality of the social, recognized that the coherence of society rests on the interdependence of activities and the moral regulation created by interaction.

The new emphasis on process did not eliminate the ideological component of the concept of society. To a greater or lesser extent, all of the thinkers of the formative period saw in society a standard for evaluating the acts and programs of individuals and other social units. In some instances the ideological functions of sociological method are quite plain, as in the case of the sociological jurisprudence of Ehrlich (1913). Ehrlich saw external and constraining social reality as existing in the "living law." A spontaneous moral order develops in the associations and groups of society as men live and work cooperatively. It is this inner order of society that is the yardstick for measuring the value of the positive law of the state. Sociological jurisprudence is conceived as a corrective to conceptual jurisprudence. The latter, in its reliance on concepts and logic, is likely to become out of step with the real moral order of society and thus fail to respond to pressing social interests and problems. [See *LAW, article on THE LEGAL SYSTEM*.]

In other cases the ideological affinities of the concept of society as process are more subtle. For example, the popularity of the social-psychological approach in the United States cannot be separated from its capacity to provide a sociological foundation for modern liberalism. Classic *laissez-faire* liberalism had been founded on the utilitarian conception of society as a collection of wills. Sociological conceptions are more suited to the defense

of either conservatism or radicalism, depending on whether social reality is conceived as an irreducible obstacle or an inexorable transformative force. The problem for modern liberalism was to justify individual freedom in the context of social regulation. The concept of society as an emergent regulative process, founded on the responsible actions of social persons, is consistent with the program of modern liberalism.

### Some contemporary approaches

Despite the developments of the formative period of sociology, relatively little progress was made in defining the concept of a *society*. "Society" remained a term for designating an emergent and constraining level of reality. Until recent decades, the main purpose of analysis was to examine the nature of social reality and its modes of constraint, not to define the units and boundaries of concrete societies as entities.

**Society as a social system.** The major technical device used in recent years to attack the problem of defining a society has been the concept of a social system. A social system is an organized set of interdependent social persons, activities, or forces. It is called a system because its organization includes mechanisms for maintaining an equilibrium or some other constancy in the relations between the units. From another perspective such mechanisms can be seen as boundary-maintaining mechanisms, for systems can be isolated as separate entities only if they maintain some constancies in the face of environmental change, that is, if they maintain some boundaries vis-à-vis the environment. If every event within a system were a direct consequence of some event outside the system, it would be impossible to draw a boundary for the system; it would be, in effect, a mere unit in a larger complex. The concept of a social system seems ideally suited for use in defining a society analytically, for it contains within it the crucial concepts of "unit" and "boundary"; to define society as a special sort of social system automatically prepares the way for identification of its units and boundaries.

The idea of a social system was used by earlier thinkers, notably Spencer and Pareto, but it has been formulated in greater detail and applied to the present problem by the modern school of structural-functionalism. The paper by Aberle and his colleagues cited earlier in this article is an example of the functional mode of attack on the problem. The approach of that paper has been more fully elaborated by Levy (1952; 1966) and is similar to a definition proposed by Parsons: "A social sys-

tem . . . which meets all the essential functional prerequisites of long term persistence from within its own resources will be called a society" (1951, p. 19).

The key concept in these definitions is "self-sufficiency." All systems are self-sufficient to some degree; the definition of the term requires some mechanisms of self-maintenance. The isolation of total societies involves the search for global complexes with the highest degree of self-maintenance and the least reliance on other social systems for their requisite resources. Local communities, administrative units, institutional spheres, and bureaucratic organizations are all relatively dependent segments of a larger whole. Total societies are dependent only on other types of systems: personalities, cultural traditions, and a physical environment. [See SYSTEMS ANALYSIS.]

**Overlapping process systems.** The search for the self-sufficient society may be futile. In fact, the concept of a *society* with exclusive boundaries may be obsolete. This is not to say that it is not valid to do comparative study over very large aggregates. Indeed, one of the achievements of twentieth-century empirical social science is the thorough demonstration that society is real in the sense that social variables relate to each other differently in "societies" with different characteristics. In this sense the concept of society no longer rests on conjecture. However, at the theoretical level the search for a universally valid definition of the nature and boundaries of a society as a self-contained unit may obscure the complexity of social life.

Many of the historic and contemporary problems in the conceptual analysis of society may be clarified by viewing society as a complex of overlapping process systems. We may abstract from the concrete interaction of concrete social persons a number of types of interaction systems. Economic, religious, political, educational, and other types of activity come to cohere into partially independent systems with units, boundaries, and mechanisms of their own. These systems overlap; and when a relatively broad range of such systems cohere around a common population, we may speak of a society. There is no reason to suppose, however, that this society will be self-contained, that it will not overlap with other societies, or that its boundaries will be uniform across its constituent systems.

It would be a mistake to regard the notion of a self-sufficient society as intrinsically absurd. One might be tempted to argue that any society engages in at least some trade and cultural exchange with at least one other society, and that therefore there are no self-sufficient societies. This argument, how-

ever, misconstrues the concept of self-sufficiency. To call a society self-sufficient implies not that it is isolated but that its social system contains within itself cultural materials and role opportunities sufficient for carrying on controlled relations with an environment (Parsons 1966).

The truth or falsehood of alternative conceptions of society is not at issue here. Rather, we are contrasting alternative ways of approaching the problems of societal analysis. Thus, an approach based on the concept of social system can be criticized for failing to make several important phenomena immediately problematic. But this is very far from saying that it causes logical difficulties so severe as to prevent analysis of these phenomena altogether.

The alternative to the social system approach is to start with the concept of population. This involves making problematic not only the degree to which the activities of a population are organized into systems, but also the units and boundaries of these systems and their forms of interdependence. Thus the emergence of a bounded, unified social system is no longer assumed but becomes an object of inquiry.

The boundaries of a society are usually drawn at the outer limits of the interdependencies and commonalities that give it coherence. Special criteria are often used to define particular types of society. Thus, in the case of the nation-state the limits of political jurisdiction are taken to define the limits of the political system and, thus, of the society. In fact, if societies are viewed as complexes of overlapping process systems, it becomes natural to accept the fact that societal boundaries are irregular. From this, one is led to consider the sources and consequences of variation in the scope of systemic boundaries (for instance, by examining the consequences of the involvement of national states in international colonial development).

Another single-criterion approach to defining the boundaries of the societal population is to adopt the social system's own normatively defined concept of membership (Parsons 1966). To this it may be objected that the members of a societal population may be involved in well-organized social systems that crosscut membership boundaries. The common solution to this problem is to treat the basic unit of society as the "person-in-role," and then to allege that behavior in boundary-crossing roles is *external* to the society. One then attempts to identify the mechanisms for segregating roles and regulating members who cross societal boundaries. Again, the focus is on how such regulation is accomplished, not on the conditions under which it will emerge or the consequences of its absence.

To define society as a set of overlapping process systems also permits flexibility in the analysis of the units of society. The utilitarian conception of society was based on the notion of the isolated individual. As early as Comte, the wisdom of this approach was called into question. Comte saw the utility of beginning with more socially relevant units; for him, the unit of society was the family. Other analysts continued this tradition in their treatment of the communal aspects of society. Later, with the development of processual concepts, segments of the actions of social persons came to be used as units of analysis. Thus, Parsons has spoken of the units of social systems as actors in roles (1951, pp. 24-26).

If society is viewed as a complex of overlapping process systems, it would appear that the ultimate social unit is the act. However, it does not follow that the intermediate units of different process systems will be the same. Society does not have a single type of unit, but many: its constituent systems have units of different types, and these differences can be of considerable analytical importance. For example, many of the strains in modern societies derive from the fact that, although families are the molecular units of modern status systems, rational market and bureaucratic systems are predicated on the evaluation of specific performances in roles. In consequence, competing bases of evaluation are present in society.

The links between units may also vary from system to system. Theories of society have postulated six major types of links between units: emotional attraction, orientations of actors to each other, shared cognitive and evaluative perspectives, mutual influence or coercion, economic or functional interdependence, and common participation in an environment. There is no reason to assume that any of these types of links constitutes the one true mechanism of social coherence. On the other hand, one or another of them may be dominant in particular process systems. This possibility is itself a source of important sociological problems: we are led to ask such questions as "What is the consequence of the expansion of systems of economic interdependence beyond the boundaries of systems based upon emotional attachments?"

The notion of a set of overlapping process systems is not by itself a satisfactory model of society. It leaves open the question of the relation between a society and other social groupings. How, for instance, is a society to be distinguished from a community? The term community has been used in a variety of ways. For some, communities are locally based units of a larger society; for others, "com-

munity" refers to some aspect of society, such as its solidarity (that is, communal) or spatial components. Others, particularly in the German sociological tradition, distinguish communities as relatively solitary types of societies [see COMMUNITY-SOCIETY CONTINUA].

It is legitimate to use the term "community" to refer to both locally based units and some aspect of the larger society. The former usage is well established in English speech. The latter usage is sometimes said to be justified by the need to establish a distinction between societies and other social entities. Institutions and special-purpose associations are said not to be societies because they have no communal components. The concept of population can be used in a similar way to distinguish societies from other sets of systems of social processes, since the latter may have sets of members without having populations in the biotic sense. A society is sustained by a population. To establish the boundaries of a societal population we may adopt a definition of population quite similar to the one employed by bioecologists: A population consists of the self-perpetuating inhabitants of a territorial area. In this context the term "self-perpetuation" implies mating, and the term "inhabitant" implies relatively permanent residence. Thus, the boundaries of a population that sustains a society are established by the limits of the largest territorial area within which mating is common and residence is relatively permanent.

These criteria establish a model that, while it does not completely correspond to any empirical population, does provide a means of clearly excluding types of groups that are not societies. Many groups do not qualify as societies because membership in them is not conferred by birth. Further, members of local communities quite often cross community boundaries for the purpose of mating and establishing new residences, while members of societies do not often cross societal boundaries for these purposes—indeed, that is why they form what I have called a population.

To start with the concept of a population is not to define a society as consisting in its population. The society is not the population but the complex systems of action in which the units of the population participate.

The next problem for the analyst is to establish the boundaries of these systems of action. In a highly organized society, which closely controls the relations between the units of its population and members of other populations, it may be useful to treat only relations within the societal population as internal to the society. On the other hand, when

societal systems become very permeable to social influences that transcend population boundaries, it is more realistic to consider the society to have irregular boundaries and to overlap other societies.

Historically, conceptions of society have had ideological implications and overtones. Perhaps this conception of society as a set of overlapping process systems is not an exception, for it seeks to call attention to the problems of the emergence of larger and more inclusive networks of social organization. As man has expanded his ecological niche there has been a continuous growth of national organization that transcends the less inclusive traditional solidarities. At the same time, cosmopolitan and international organization has outrun national boundaries. The modern world is regularly upset by shock waves reverberating from local traditional cleavages through national political systems; sometimes these shock waves reach the international arena. If sociological analysis is adequately to represent the constraints imposed by this emergent global level of social reality, its analytical conceptions must not be inflexibly tied to the concept of the national boundary.
